## **PREFACE**

This quality report is the intermediate quality report of EU-SILC 2009 in Poland. It follows the structure outlined in the Commission Regulation No. 1177/2003.

This report consists of four chapters.

The first chapter describes the common cross-sectional indicators.

The second chapter deals with accuracy i.e. discusses all the factors that affect the precision of estimations and results.

The third chapter reports on comparability and indicates all the differences between the standard EU definitions and those applied in the polish survey.

The fourth and last chapter, reporting on coherence, presents the comparison of the EU-SILC 2009 data with external sources.

As this is the fourth intermediate quality report on EU-SILC in Poland, some chapters and sections resemble the corresponding chapters and sections of the previous reports.

## 1. COMMON CROSS-SECTIONAL EUROPEAN UNION INDICATORS

### 1.1. Common cross-sectional EU indicators based on the cross-sectional component of EU-SILC 2009

	Indicator	Value
1	At-risk-of-poverty rate after social transfers - total	17.1
2	At-risk-of-poverty rate after social transfers - men total	16.9
3	At-risk-of-poverty rate after social transfers - women total	17.4
4	At-risk-of-poverty rate after social transfers - 0-17 years	23.0
5	At-risk-of-poverty rate after social transfers - 18-64 years	16.0
6	At-risk-of-poverty rate after social transfers – men, 18-64 years	16.0
7	At-risk-of-poverty rate after social transfers – women, 18-64 years	16.0
8	At-risk-of-poverty rate after social transfers - 65+ years	14.4
9	At-risk-of-poverty rate after social transfers – men, 65+ years	10.9
10	At-risk-of-poverty rate after social transfers – women, 65+ years	16.5
11	At-risk-of-poverty threshold – single	10742 PLN
12	At-risk-of-poverty threshold - 2 adults, 2 children	22557 PLN
13	Relative median at-risk-of-poverty gap - total	22.7
14	Relative median at-risk-of-poverty gap - men total	23.7
15	Relative median at-risk-of-poverty gap - women total	21.8
16	Relative median at-risk-of-poverty gap - 0-17 years	23.7
17	Relative median at-risk-of-poverty gap - 18-64 years	24.0
18	Relative median at-risk-of-poverty gap - men, 18-64 years	24.1
19	Relative median at-risk-of-poverty gap - women, 18-64 years	23.9
20	Relative median at-risk-of-poverty gap - 65+ years	15.0
21	Relative median at-risk-of-poverty gap - men, 65+ years	14.6
22	Relative median at-risk-of-poverty gap - women, 65+ years	15.3
23	Inequality of income distribution S80/S20 income quintile share ratio	4.96
24	In work at-risk-of-poverty rate - total	11.0
25	In work at-risk-of-poverty rate - men total	12.1
26	In work at-risk-of-poverty rate - women total	9.8
27	Relative median income ratio people aged 65+/0-64	0.92
28	Relative median income ratio people aged 65+/0-64 - men	1.00
29	Relative median income ratio people aged 65+/0-64 - women	0.87
30	Aggregate replacement ratio pensions 65-74/earnings 50-59	0.56
31	Aggregate replacement ratio pensions 65-74/earnings 50-59 - men	0.63
32	Aggregate replacement ratio pensions 65-74/earnings 50-59 - women	0.55
	<b>Before social transfers except old-age and survivors' benefits</b>	
33	At-risk-of-poverty rate before social transfers - total	23.6
34	At-risk-of-poverty rate before social transfers - men total	23.4
35	At-risk-of-poverty rate before social transfers - women total	23.7
36	At-risk-of-poverty rate before social transfers - 0-17 years	30.1
37	At-risk-of-poverty rate before social transfers - 18-64 years	23.0
38	At-risk-of-poverty rate before social transfers - men, 18-64 years	23.2
39	At-risk-of-poverty rate before social transfers - women, 18-64 years	22.7
40	At-risk-of-poverty rate before social transfers - 65+ years	17.3
41	At-risk-of-poverty rate before social transfers - men, 65+ years	13.0
42	At-risk-of-poverty rate before social transfers - women, 65+ years	19.9

<b>Indicator</b>		<b>Value</b>
<b>Before social transfers including old-age and survivors' benefits</b>		
43	At-risk-of-poverty rate before social transfers - total	<b>42.6</b>
44	At-risk-of-poverty rate before social transfers - men total	<b>40.2</b>
45	At-risk-of-poverty rate before social transfers - women total	<b>44.8</b>
46	At-risk-of-poverty rate before social transfers - 0-17 years	<b>36.4</b>
47	At-risk-of-poverty rate before social transfers - 18-64 years	<b>35.9</b>
48	At-risk-of-poverty rate before social transfers - men, 18-64 years	<b>34.8</b>
49	At-risk-of-poverty rate before social transfers - women, 18-64 years	<b>37.0</b>
50	At-risk-of-poverty rate before social transfers - 65+ years	<b>84.4</b>
51	At-risk-of-poverty rate before social transfers - men, 65+ years	<b>83.1</b>
52	At-risk-of-poverty rate before social transfers - women, 65+ years	<b>85.2</b>
53	Mean equivalised disposable income	<b>21015 PLN</b>

## **2. ACCURACY**

### **2.1. Sample design**

#### ***2.1.1. Type of sampling design***

The two-stage sampling scheme with differentiated selection probabilities at the first stage was used. Prior to selection, sampling units were stratified.

#### ***2.1.2. Sampling units***

The first-stage sampling units (primary sampling units - PSU) were enumeration census areas, while at the second stage dwellings were selected. All the households from the selected dwellings are supposed to enter the survey.

#### ***2.1.3. Stratification and substratification criteria***

The strata were the voivodships (NUTS2) and within voivodships primary sampling units were classified by class of locality. In urban areas census areas were grouped by size of town, but in the five largest cities districts were treated as strata. In rural areas strata were represented by rural gminas (NUTS5) of a subregion (NUTS3) or of a few neighbouring poviats (NUTS4). Altogether 211 strata were distinguished.

#### ***2.1.4. Sample size and allocation criteria***

It was decided that the sample should include about 24 000 dwellings in the first year of the survey. Proportional allocation of dwellings to particular strata was applied. The number of dwellings selected from a particular stratum was in proportion to the number of dwellings in the stratum. Furthermore, the number of the first-stage units selected from the strata was obtained by dividing the number of dwellings in the sample by the number of dwellings determined for a given class of locality to be selected from the first-stage unit. In towns with over 100 000 population 3 dwellings per PSU were selected, in towns with 20-100 thousand

population – 4 dwellings per PSU, in towns with less than 20 000 population – 5 dwellings per PSU, respectively. In rural areas 6 dwellings were selected from each PSU. Altogether 5912 census areas and 24044 dwellings were selected for the sample in the first year of the survey. The subsample 5 selected for the survey in 2006 to replace the subsample 1 consisted of 1476 census areas and 6002 dwellings. Then, in 2007 the subsample 6 replaced the subsample 2 and consisted of 1478 census areas and 6008 dwellings. For the 2008 survey the subsample 3 was replaced by the subsample 7. This new subsample consisted of 1479 census areas and 6016 dwellings. For the 2009 survey the subsample 4 was replaced by the subsample 8 which consisted of 1479 census areas and 6017 dwellings.

### ***2.1.5. Sample selection schemes***

Census areas were selected according to the Hartley-Rao scheme. Prior to selection, census areas were put in random order for each stratum separately and then the determined number of PSUs was selected with probabilities proportionate to the number of dwellings. Then in each of the census areas belonging to the PSU sample dwellings were selected using the simple random selection procedure.

### ***2.1.7. Renewal of sample: rotational groups***

The selected sample of first-stage units was divided into four subsamples, equal in size. Starting from 2006 one of the subsamples was eliminated and replaced with a new one, selected independently as described above. For the 2006 survey the subsample 5 was selected as a replacement of the subsample 1. Then, for the 2007 survey the subsample 6 was selected to take place of the subsample 2. For the 2008 survey the new subsample 7 replaced subsample 3. For the year 2009 the new subsample 8 replaced the subsample 4.

### ***2.1.8. Weightings***

#### *Design factor*

Design factor – DB080 is equal to the dwelling sampling fraction reciprocal in the h-th stratum i.e.

$$f_h = \frac{n_h * m'_h}{M_h},$$

$$DB080 = \frac{1}{f_h}$$

where:

$n_h$  - number of PSUs selected from the h-th stratum,

$m'_h$  - number of dwellings selected from a PSU in the h-th stratum,

$M_h$  – number of dwellings in the h-th stratum.

### Non-response adjustments

DB080 weights were then adjusted with the use of household non-response rates estimated for each class of locality separately:

Code of class of locality (p)	Class of locality	Completeness rate (cr <sub>p</sub> =R <sub>ap</sub> *Rh <sub>p</sub> )
	Poland	0.654
1	Warsaw	0.404
2	Towns 500 000 – 1 000 000 inhabitants	0.535
3	Towns 100 000 – 500 000 inhabitants	0.581
4	Towns 20 000 – 100 000 inhabitants	0.637
5	Towns less than 20 000 inhabitants	0.665
6	Rural areas	0.787

The adjusted weights were calculated according to the formula:

$$DB080_p^{corrected} = \frac{DB080_p}{Ra_p * Rh_p},$$

Weights DB080 and DB080<sup>corrected</sup> were calculated for the subsample 8. The next step consisted in calculating the weights DB090 and RB050 for the households of the subsample 8 with the use of the integrated calibration method. For the subsamples 6 surveyed for the third time and 7 surveyed for the second time and the subsample 5 surveyed for the fourth time the base weights were determined by the correction of the base weights from the previous year.

For the subsample 7 the following method was used:

The base weight of 2008 is equal to RB050 multiplied by 4. This weight was then adjusted by non-response and households' and individuals' falling out of the population surveyed. The calculations were made on the subsamples of the so called sample persons i.e. those who were in the surveyed sample at the age of 14 and over in 2008 and who should be surveyed in 2009. The modifying factor was determined according to the class of locality and took the form:

$$\frac{R(1)_p - M}{R(2)_p}$$

where:

R(t)<sub>p</sub> – estimated number of respondents belonging to the sample person group in the p-th class of locality in the subsample surveyed for the t-th time,

M – estimated number of sample persons who belonged to the surveyed population in the first year and in the next year were out of the survey scope.

The base weights of 2008 were used for the calculation of numerator and denominator. The above expression is the reciprocal of the empirical estimate of probability that a given person will be interviewed again in the second year of the survey. In the second stage of the base weight calculation for the second year of the survey children of “sample persons” received the weights of mothers and “co-residents’ i.e. additional persons included in the household surveyed were ascribed zero weights. Then the respondents’ base weights were averaged and all the members of a given household were ascribed such a mean weight. Then for the weights thus obtained the trimming of extreme weights was applied.

For the subsamples 5 and 6 (surveyed for the fourth and third time respectively) the algorithm based on the method described for the subsample 7 was used. Additionally, re-entries, i.e. persons who were surveyed in 2007, not surveyed in 2008, and surveyed again in 2009, were taken into account. The base weights for such persons were computed by correction of base weights from 2007 on data for 2007 and 2009 (without information from 2008). Inclusion of re-entries in the subsamples surveyed in 2009 brought about the necessity of to make an additional correction of the base weights for persons surveyed in the three successive years. Coefficients of these corrections were computed separately according to classes of locality as ratios: weighted number of respondents surveyed in all the three years to the weighted number of respondents in the last survey year (i.e. with re-entries); the weight used in these calculations was the weight RB050 for 2007. The coefficients thus computed are shown in the table below:

<b>Class of locality</b>	<b>Correction for subsample 5</b>	<b>Correction for subsample 6</b>
1	0.972	0.954
2	0.992	0.991
3	0.979	0.992
4	0.997	0.997
5	0.988	0.998
6	0.993	0.997

The last stage of the base weight calculation for the fourth year of the survey consisted in receiving weights of mothers by children of “sample persons” and zero weights by “coresidents’ i.e. additional persons included in the households. Then the respondents’ base weights were averaged and all the members of a given household were ascribed such a mean weight. For the weights thus obtained the trimming of extreme weights was applied.

The last stage of calculations consisted in combining the four independent subsamples, applying the integrated calibration as described below (for the sample 8 repeatedly) and trimming. As a result, DB090 and RB050 weights are obtained for households and individuals from the samples 5, 6, 7 and 8.

### Adjustments to external data

Using the integrated calibration method (in hyperbolic sinus version), weights were calculated for individuals and for households simultaneously. To do this, the information about households was used (4 size categories: 1-person, 2-person, 3-person and 4- and more person households) and number of persons by age and gender (15 age groups: under 16, 16-19 years, then eleven 5-year groups, 75 years and over). This information at the level of NUTS2, additionally classified by urban/rural areas, was derived from the 2002 Census and current demographic estimates.

### Final cross-sectional weights

In EU-SILC 2009 the following cross-sectional weights were calculated:

DB090 – weight for households,

RB050 – weight for all household members,

$RB050_{ij} = DB090_i$

where:

i – household number,

j – person number in the i-th household.

PB040 – weight for respondents at the age of 16 and over who had individual interview. This weight equals the weight RB050.

RL070 – weight for children at the age of 0–12 years. It is obtained by the adjustment of RB050 weight in 26 groups, i.e. 13 years of birth and gender.

#### **2.1.9. Substitutions**

No substitution was applied if the household did not enter the survey.

## **2.2. Sampling errors**

### **2.2.1. Standard error and effective sample size**

Estimation of standard errors was based on a resampling approach. We used a bootstrap method which resamples 500 times from each stratum  $n_h - 1$  PSU's (primary sampling units) with replacement (method of McCarthy and Snowden (1985)), where  $n_h$  denotes the sample size of PSU in the  $h$ -th stratum. After resampling the original weights were properly rescaled and bootstrap variance estimate of the corresponding indicator was obtained by the usual Monte Carlo approximation based on the independent bootstrap replicates. Computations were carried out using SAS software. Additionally, we implemented the linearization method of variance estimation for the main poverty indicators, and the results of comparisons with those obtained by the bootstrap method showed they were very similar.

Indicator	Value	Standard error	Achieved sample size	Design effect	Effective sample size
At-risk-of-poverty rate after social transfers - total	17.14	0.45	38541	4.26	9050

## **2.3. Non-sampling errors**

### ***2.3.1. Sampling frame and coverage errors***

The samples for EU-SILC were selected from the sampling frame based on the TERYT system, i.e. the *Domestic Territorial Division Register*. Two kinds of primary sampling units (PSU) were distinguished in the sampling frame:

- about 178 000 *CEA* – *census enumeration areas* with about 68 dwellings each,
- about 33 000 *ESD* – *enumeration statistical districts*, with about 377 dwellings each.

The whole territory of Poland is divided into enumeration statistical districts and census enumeration areas. In EU-SILC census enumeration areas are used as primary sampling units. The secondary sampling units are dwellings. For each census enumeration area a list of dwellings was made up to form the secondary sampling frame. All the households from the selected dwellings are supposed to enter the survey.

The TERYT system is updated annually with respect to the territorial division into statistical districts and census enumeration areas. The lists of dwellings, names of towns, villages and streets are updated. Other changes due to new construction, dismantle of buildings and administrative division modifications are also introduced.

The sample for EU-SILC 2005 was selected in September 2004 from the sampling frame updated as for January 1, 2004. In the sample selected some 6.8% of dwellings were found to be non-existing (cancelled, changed for non-residential units) as well as uninhabited or temporarily inhabited, while in the sample 5 selected in 2005 for the 2006 survey about 6.2% of such dwellings were recorded. In the sample 6 selected for the 2007 survey there were about 7% of such dwellings, and in the sample 7 selected for the 2008 survey there were about 6.3% of such dwellings. In the new subsample 8 selected for the 2009 survey 7.5% of dwellings were found to be non-existing (cancelled, changed for non-residential units) as well as uninhabited or temporarily inhabited; 1% of selected dwellings had incorrect addresses.

### ***2.3.2. Measurement and processing errors***

As with any other statistical survey, EU-SILC may be burdened with non-sampling errors which occur at various stages of the survey and which cannot be eliminated completely. This mainly applies to interviewers' errors at the stage of collecting the information, errors due to the respondents' misunderstanding of questions and inaccurate or sometimes even false answers as well as the errors taking place at the stage of data recording.

After the household and individual interview completion the respondents were obliged to answer a few questions concerning interview performance. On the basis of this material it is possible to state that about three quarters of respondents (83% of those filling in the household questionnaire and 81% of those filling in the individual questionnaire) showed a favourable attitude towards the survey, while about 2% (both in the case of the household and individual interview) were unwilling towards it. In the interviewers' opinion, in about 74% of questionnaires (both household and individual ones) the quality of non-income data collected could be recognised as good or very good and in 2% - as doubtful. The quality of income data was evaluated as slightly worse, mainly because of item non-response.

It should also be pointed out that, in our opinion, the quality of data concerning net income categories is much higher than in the case of gross income. The reason is that non-response to the highest degree affected the information on taxes and social and health insurance contributions.

In Poland the EU-SILC 2009 was carried out in May/June.

Very much like in 2005, 2006, 2007 and 2008, it was a non-obligatory, representative survey of individual households, performed by a face-to-face interview technique with the use of paper form questionnaires (the so called PAPI method). Two types of questionnaire - individual and household questionnaire - were applied.

The organisation and performance of the survey in the field was within the responsibility of regional statistical offices. Most of the interviewers were regular employees of the statistical offices having experience in other social surveys. The fieldwork was preceded by a series of trainings. Regional survey coordinators were instructed by the staff members of the CSO Labour and Living Conditions Division and then the regional survey coordinators trained interviewers at the regional statistical offices. The interviewers received written instructions concerning the survey performance.

Interviewers' visits to households were preceded by the introductory letter from the CSO President.

Small gifts were given to the families participating in the survey. Each statistical office chose the type of gift for its respondents.

Data recording from the questionnaire forms was carried out with the use of Microsoft Visual FoxPro version 9 operating under the WINDOWS system. The following two applications were designed:

- The so called interviewer's application – to be used by the interviewers to record and check the data from their areas with the use of Laptops and PCs. The data were recorded on the local disk in the VFP database. After the work was completed, the data were transmitted using Web services to the MS SQL server for the national database;
- The so called server application – to be used by the staff of Statistical Offices recording the data directly for the national database and for those supervising the regional data preparation; this application was published in the CITRIX server and made accessible with the customer's software.

Both applications shared a number of modules.

The server application had a module which allowed for works (such as checking, viewing, making statements) on the national data (from all the voivodships). The national file completeness was also checked with the use of Microsoft Visual FoxPro. Additional check-up was made with SAS checking programmes.

Tables of EU-SILC results were compiled with the use of: SAS, SPSS, Microsoft Visual FoxPro.

### 2.3.3. Non-response errors

#### Achieved sample size

Sample size	Rotational group				
	5	6	7	8	Total
A	3256	3169	3327	3472	13224
B	7401	7105	7283	7440	29229
C	9730	9390	9570	9851	38541

A - number of households for which an interview is accepted for the database

B - number of persons at the age of 16 years or more who are members of the households for which the interview is accepted for the database, and who completed an individual interview.

C - number of persons who are members of the households for which the interview is accepted for the database.

#### Unit non-response

- Household non-response rates  $NRh = [1 - (Ra * Rh)] * 100$ ,

$Ra = 0.995$

$Rh = 0.830$

$Ra$  – the address contact rate

$Rh$  – the proportion of complete household interviews accepted for the database

$NRh = 17.38$

- Individual non-response rates  $NRp = (1 - Rp) * 100$ ,

$Rp = 0.923$

$NRp = 7.719$

$Rp$  – the proportion of complete personal interviews within the households accepted for the database

- Overall individual non-response rates  $*NRp = [1 - (Ra * Rh * Rp)] * 100$ ,

$*NRp = 23.76$

### *Adopted methods of income variable imputation*

Imputation is aimed at obtaining complete records at the level of target variables. Target variables do not simply reflect questionnaire variables and their calculation algorithm is often complicated, although it principally consists in aggregation. So it is necessary to decide what aggregation level the imputation should take place at. There are three possible options:

- the level of questionnaire variables,
- the level of partly aggregated components,
- the level of ready-calculated target variables.

Since the only formal requirement is to obtain imputed target variables, all the above options are permissible and practicable, depending on the specific character of variables. However, the most frequent practice is the imputation at the level of questionnaire variables. There are certain arguments for this approach, on condition that the quantity of data and calculation algorithm details allow for it without much complication.

First of all, imputation at the lowest aggregation level can be desirable for the principal reasons related to the quality of imputation when:

- a target variable implies components of different character (i.e. taking different but rather predictable values, e.g. various social benefits, or dependent on a number of explanatory variables and thus easier to be modelled separately);
- target variables include many components and it is often the case that some of them have the missing values, while others – the correct ones. The correct values would be missed during the imputation of an aggregated variable.

Secondly, there are practical arguments for the imputation of disaggregated variables, as the same data serve as a basis for calculating national variables differing from the Eurostat's target variables. Thus the imputation of disaggregated components may be required so as to ensure the imputed data needed for other calculations.

The imputation at the target variable level is carried out only when the above circumstances do not occur or when overcoming the practical difficulties is easier than the imputation of disaggregated data.

There are several methods of component imputation. They can be classified as deterministic and stochastic methods. In case of deterministic methods the selected method and the set of explanatory variables (algorithm) clearly determine the imputation values for each record. In stochastic methods the imputation value is determined with the use of a random component. That is why it may happen that with the same algorithm and the same data file each algorithm realisation will give slightly different imputation values. Although the stochastic methods slightly increase estimator variance (introducing an additional random error component), they do not distort variance or original data distribution characteristics and allow for the correct estimation of random error. Deterministic imputation brings about variable variance reduction in the file and random error underestimation; it also distorts to a greater extent the correlation structure (increasing correlations with explanatory variables). According to item 2.7 of Regulation 1981/2003 it is recommended that for EU-SILC imputation the methods retaining distribution characteristics should be applied, which means the preference for the stochastic methods.

Out of the stochastic methods the following were used in the task presented here:

- Hot-deck method

Random selection of a representative (donor) out of the correct records.

If auxiliary categorizing variables are used in the hot-deck method, a random representative is selected out of the records showing adequate values of auxiliary variables. If it is not possible to find a donor with the equivalent values for all the auxiliary variables, the so called sequence approach is applied. The categorising variables were ranked from the most to the least significant ones. If there are no donors available, categorization is carried out with the subsequent explanatory variables being left out, starting from the least significant ones so as to obtain a subset containing donors.

- Stochastic regression imputation

Auxiliary variables are the explanatory variables of the regression model. The model takes the linear form or the logarithmic transformation is used. It is fitted on the basis of the correct records. The imputed value (or its logarithm in the case of transformed models) is a sum of the theoretical value derived from the model and a randomly selected model residual. The set of records of which the residual is selected is restricted to those which are nearest to the record imputed for the theoretical value derived from the model.

Out of the deterministic methods the following are applied:

- Regression deterministic imputation

The theoretical value from the model is adopted as the imputation value.

- Deduction imputation

The imputation value is directly determined on the basis of the relationships between variables.

In the case of imputation at the target variable level or imputation of the most significant components of target variables, stochastic imputation is applied in order to retain the variable properties distribution as required by Regulation 1981/2003.

The application of stochastic regression imputation requires a model which describes well the formation of a variable with relatively small variance of an error term and good statistical qualities. With high variance of an error term, there is a danger of getting accidental values which are not typical of the correct part of the dataset. That is why in the cases where, in accordance with the assumption referred to above, stochastic imputation is required, the hot-deck method is used in preference to regression imputation. This is particularly justified when the number of records for imputation is rather low, or when the number of correct records is too small for a suitable model fitting.

Stochastic regression imputation is most widely used for incomes from hired employment, as:

- it is an important category of income, declared by a significant rate of respondents which, if present, has a significant share in the total household's income;
- this category can be successfully modelled with the use of the variables included in the questionnaire;
- there is a large (absolute) number of missing data, the percentage, however, being rather small; a large number of correct records make it possible to design a well-fitted model.

In case of incomes from hired employment stochastic regression imputation is applied to the majority of records with missing items, both those for which observations from the previous year are available (panel sample) and the new ones in the sample. In case of other income categories stochastic regression imputation is used as the basic imputation method when incomes of the same type for a given person/household are known from the previous year. If such income data from the previous year are not available, the hot-deck method is applied.

The hot-deck method is also applied when the income data are known from the previous year but a suitable model fitting is difficult. In such a case the income from the previous year is used as a grouping variable. If the quantitative categorizing variable is applied in the hot-deck method, the categorization criterion is a break-down into deciles.

Considering a relatively wide application of the stochastic regression imputation, supplementary protection against the effects of potential insufficient model adequacy was introduced. The residuals are not generated from the distribution of residuals for the whole sample, but they are selected from a restricted subset. Although, in an ideal model, residuals should be in the form of white noise, showing no trend whatsoever, in reality, some trends can be observed in the distribution of residuals which are not detected by the model (like those related to non-linearity of relationships which cannot be removed by known transformations).

In such a case, if we used residuals from the whole range, we could combine a particular theoretical value obtained from the model with the residual which occurs in the whole distribution but is quite improbable in combination with this particular theoretical value. So we could generate values significantly diverging from the real variable distribution. The use of residuals from the restricted range only reduces that risk.

Deterministic imputation is applied where missing data concern less significant components of target variables (taxes, burdens to the main component, additions, etc.) in the situation when the main component is known. In such cases deterministic regression imputation is usually applied. Gross/net conversion is carried out with the use of the deterministic regression method. Deduction imputation is employed in rare cases of obvious relationships and can be treated as a supplementary stage of data editing.

The explanatory variables in the models and the grouping ones in the case of hot-deck method were selected so as to represent the relationships which, according to logics and knowledge about the phenomena studied, should occur in the data set, taking into account accessibility of the potential variables in the questionnaire. The relationships were tested on the file of correct data and in the majority of cases they proved to be significant. Some of the explanatory variables were retained, even if their impact on the imputed variable has not been statistically confirmed, if they expressed an economically important relationship or provided a grouping condition (interpretation criterion) in the calculation algorithm.

For the persons and households not surveyed in the previous year (a new sample, new household members, persons who could not be interviewed) or for those who did not gain a particular type of income in the previous year, explanatory variables derived from the current data file were applied. Wherever the same type of income was found in the data for the previous year, its value was treated as the main explanatory (categorizing) variable, both in the case of variables subjected to regression imputation and the hot-deck method. The current variables can be treated as additional explanatory variables.

### ***Imputation of the missing individual questionnaires***

The imputation of the missing individual questionnaires was carried out with the use of the hot-deck method. A wide set of variables providing household's characteristics (main source of maintenance) and variables from R set determining the person's position in the household and on the labour market was used as the categorization criterion. All the primary target variables related to the donor were transferred to the taker's record and then they were used for the calculation of household's total income. The records obtained as a result of imputation of the missing questionnaires were attached to the individual income data files, while the income data were included in the total income indicated in the household data file. this made the files coherent.

*Total item non-response and number of observations in the sample at unit level of common cross-sectional European indicators based on cross-sectional component of EU-SILC, for equivalised disposable income*

## 2.4. Mode of data collection

EU-SILC is a non-obligatory, representative survey of individual households, performed by a face-to-face interview technique with the use of paper form questionnaires (the so called PAPI method). Two types of questionnaire: individual and household questionnaire are applicable.

### Distribution of RB250 and RB260

#### - RB250 – Data status

<b>RB250</b>	<b>Rotational group</b>				
	5	6	7	8	<b>Total</b>
Information completed only from interview (11)	7401	7105	7283	7440	29229
Individual unable to respond (illness, incapacity, etc) (21)	23	32	44	33	132
Refusal to co-operate (23)	324	304	323	327	1278
Person temporarily away and no proxy possible (31)	186	162	147	210	705
No contact for another reason (32)	68	98	61	99	326
Information not completed: reason unknown (33)	3	0	1	0	4
<b>Total</b>	8005	7701	7859	8109	31674

#### - RB260 – Type of interview

<b>RB260</b>	<b>Rotational group</b>				
	5	6	7	8	<b>Total</b>
Face to face (1)	5912	5739	6026	6159	23836
Proxy interview (2)	1489	1366	1257	1281	5393
<b>Total</b>	7401	7105	7283	7440	29229

As for individual interviews, in 2009 a relatively high share (18,5%) of proxy interviews was noted. This was thoroughly discussed with the survey coordinators in the field.

The interviewers decided on proxy interviews only if the substitute respondents were well informed about the situation in the household and there was no other possibility to get the information. Proxy interviews were performed in the following situations:

- no contact with the respondent because of long-term absence (e.g. work in another town or abroad);
- respondent's disability, illness or pathology (such as alcoholism);
- according to other members of the household, the respondent was only available late at night and was not willing to participate in such a long interview, while at the same time the proxy could provide detailed information, even based on the documents, such as tax statements.

## **2.5. Interview duration**

The average household interview duration was about 33 minutes, while the average individual interview duration was about 21 minutes. In total the average time needed to carry out a household interview and individual interviews with persons at the age of 16 years and over was 80 minutes.

This value exceeded significantly that assumed in the regulation, which results from the fact that in the Polish SILC all the information is collected during the interview. The questionnaire parts covering social benefits and self-employment (in and outside farming) have been expanded by many auxiliary questions which help to answer but, on the other hand, prolong the interview. The problem of the interview duration was already pointed out in the Intermediate Quality Reports for EU-SILC 2005, 2006, 2007 and 2008.

### **3. Comparability**

#### **3.1. Basic concepts and definitions**

##### *The reference population*

No difference to the common definition.

The survey unit was a household and all the household members who had completed 16 years of age by December 31, 2008.

The survey did not cover collective accommodation households (such as boarding house, workers' hostel, pensioners' house or monastery), except for the households of the staff members of these institutions living in these buildings in order to do their job (e.g. hotel manager, tender etc.).

The households of foreign citizens should participate in the survey.

##### *The private household definition*

No difference to the common definition.

Household is a group of persons related to each other by kinship or not, living together and sharing their income and expenditure (multi-person household) or a single person, not sharing his/her income or expenditure with any other person, whether living alone or with other persons (one-person household).

Family members living together but not sharing their income and expenditure with other family members make up separate households.

The household size is determined by the number of persons comprised by the household.

##### *The household membership*

No difference to the common definition.

The household composition accounted for:

- persons living together and sharing their income and expenditure who have been in the household for at least 6 months (either the real or the intended time of staying in the household should be considered),
- persons absent from the household because of their occupation, if their earnings are allocated to the household's expenditure,
- persons at the age of up to 15 years (inclusive), absent from the household for education purposes, living in boarding houses or private dwellings,
- persons absent from the household at the time of the survey, staying at education centres, welfare houses or hospitals, if their real or intended stay outside the household is less than 6 months.

The household composition did not account for:

- persons at the age of over 15 years, absent from the household for education purposes, living in boarding houses, students' hostels or private dwellings,
- men in military service (those performing substitute military service working in companies and living at home are included in the household),
- persons in prison,
- persons absent from the household at the time of the survey, staying at education centres, welfare houses or hospitals, if their real or intended stay outside the household is more than 6 months,
- persons (household's guests) staying in the household at the time of the survey who have been or intended to be there for less than 6 months,
- persons renting a room, including students (unless they are treated as household members),
- persons renting a room or bed for the time of work in a given place (including such works as land melioration, geodetic measurements, forest cut-down or building constructions),
- persons living in the household and employed as au pairs, helping personnel on the farm, craft apprentices or trainees.

*The income reference period(s) used*

No difference to the common definition.

The income reference period was last calendar year (2008).

*Reference period for taxes on income and social insurance contributions*

The reference period for income tax prepayment and compulsory social insurance contributions is the year 2008. The account clearance with the Treasury Office (including payments and returns) effected in 2008 refers to the income for 2007.

*The reference period for taxes on wealth*

No difference to the common definition.

Taxes on wealth paid during the income reference period (2008) were recorded.

*The lag between the income reference period and current variables*

The lag between the income reference period and current variables is about 5 months.

*The total duration of the data collection of the sample*

EU-SILC was performed on the territory of the whole country between May 4 and June 26 2009.

*Basic information on activity status during the income reference period*

No difference to the common definition.

## 3.2. Components of income

### 3.2.1. Differences between the national definitions and standard EU-SILC definitions:

#### Total gross household income HY010

No difference to the common definition.

#### Total disposable household income HY020

No difference to the common definition.

#### Total disposable household income before social transfers, except old-age and survivor's benefits HY022

No difference to the common definition.

#### Total disposable household income before social transfers including old-age and survivor's benefits HY023

No difference to the common definition.

In accordance with EU-SILC 065 (2009 operation), the new income components, mandatory from 2007 operation onwards:

- PY020G – NON-CASH EMPLOYEE INCOME;
- PY030G – EMPLOYER'S SOCIAL INSURANCE CONTRIBUTION;
- PY070G – VALUE OF GOODS PRODUCED FOR OWN CONSUMPTION;
- PY080G – PENSION FROM INDIVIDUAL PRIVATE PLANS;
- HY030G – IMPUTED RENT;
- HY100G – INTEREST REPAYMENTS ON MORTGAGE

have been recorded at component level only and they are not included in the household's total income (variables: HY010G; HY020G; HY22G; HY023G).

#### Imputed rent HY030

This variable has been calculated based on the econometric model.

#### Regular inter-household cash transfer received HY080 and regular inter-household cash transfer paid HY130

Since EU-SILC 2008 two additional variables were distinguished from both variables on regular cash transfers (HY080 and HY130): Alimonies received - compulsory + voluntary (HY081), and Alimonies paid – compulsory + voluntary (HY131).

HY081 variable is contained in the variable HY080 and similarly, HY131 is contained in HY130.

#### Employee cash or near cash income PY010

This variable does not account for:

- assistance for foster families; since granting the benefit is not connected with quitting the job, this benefit has been qualified to the category of „Family related allowances (HY050),
- benefit granted to the families when the only person providing income for the family is called up to the active military service; as this benefit is only granted when the only family supporter has been called to the military service, it has been included in the category of „Family related allowances (HY050).

#### Non-cash employee income PY020

Company car (PY021) – the information on the private use of the company car is collected in the individual questionnaire. The respondent gives the estimated amount he/she has gained by using the company car for private purposes. In case of the missing value (the respondent was using the company car but did not estimate the amount gained), imputation is applied with the use of hot-deck and regression imputation with simulated residuals methods;

#### Cash benefits or losses from self-employment PY050

The data on income from self-employment were collected in two different ways: the respondents were asked to declare the company's costs and profits and also the amount of money gained from self-employment which was allocated to the household's expenditure. After a detailed analysis of data it was decided that the income from self-employment would be equal to the amount allocated to the household's needs.

#### Survivor's benefits PY110

Death grants are not included in the income because the whole sum is used to cover the cost of the funeral.

#### Sickness benefits PY120

Sickness and childcare benefits are not included (a childcare benefit is granted to the working parent of a sick child), because they are paid by the employer and cannot be detached from the income from hired employment. Therefore, they are accounted for in the income from hired employment.

*All the other variables not listed above*

#### VARIABLES ON THE ECONOMIC STATUS

In 2009 the recommendations from EU-SILC 065 (2009 operation) concerning economic status variables were applied.

The variables introduced:

**PL031: SELF-DEFINED CURRENT ECONOMIC STATUS** (replaced PL030)  
**PL073: NUMBER OF MONTHS SPENT AT FULL-TIME WORK AS EMPLOYEE**  
**PL074: NUMBER OF MONTHS SPENT AT PART-TIME WORK AS EMPLOYEE**  
**PL075: NUMBER OF MONTHS SPENT AT FULL-TIME WORK AS SELF-EMPLOYED  
(INCLUDING FAMILY WORKER)**  
**PL076: NUMBER OF MONTHS SPENT AT PART-TIME WORK AS SELF-EMPLOYED  
(INCLUDING FAMILY WORKER)**  
**PL086: NUMBER OF MONTHS SPENT AS DISABLED OR/AND UNFIT TO WORK**  
**PL088: NUMBER OF MONTHS SPENT IN COMPULSORY MILITARY SERVICE**  
**PL089: NUMBER OF MONTHS SPENT FULFILLING DOMESTIC TASKS AND CARE  
RESPONSIBILITIES**  
**PL111: NACE REV.2** (since 2009 without PL110)  
**PL211: MAIN ACTIVITY (JANUARY – DECEMBER)** –replaced PL210

Additionally, the following variables were removed:

**PL070: NUMBER OF MONTHS SPENT AT FULL-TIME WORK**  
**PL072: NUMBER OF MONTHS SPENT AT PART-TIME WORK**

No difference to the common definition.

### ***3.2.2. The source or procedure used for the collection of income variables***

The income data were collected during the interviews with respondents. The target income variables were split into components corresponding to particular benefits applicable in the Polish conditions.

### ***3.2.3. The form in which income variables at component level have been obtained***

The respondents were asked to give the net incomes and contributions (income tax prepayments and compulsory social insurance). Only in the case of income from rental of a property (HY040) the respondents were asked to give the gross income and the amount of tax paid.

### ***3.2.4. The method used for obtaining income target variables in the required form***

The gross income was obtained by summing up net value, income tax prepayments and compulsory social insurance contributions. If the information on tax and insurance contributions was missing, the amounts were imputed on the basis of the results obtained. Only in the case of income from rental of property, the tax paid was subtracted from the gross income.

## 4. COHERENCE

### 4.1. Comparison of EU-SILC and HBS results

The objective of this section is to compare HBS (Household Budget Survey) and EU-SILC results.

Up to 2004 the HBS provided the main source of data on the living conditions of the Polish population, among others on incomes, dwelling conditions and households' equipment.

The HBS has been regularly conducted every year since 1993 up to now with the use of the rotational method. The households are surveyed in the two year panel.

In HBS the main source of data on income and expenditure is provided by the diaries, while that concerning dwelling-related expenditure and utilities – by BR-01a questionnaire. In addition, three other questionnaires are filled in.

When comparing these two sources we must take into account the discrepancies. The differences are to great extent brought about by the methodological diversity. Here are the main diverging points:

- Different reference periods for income variables – in HBS the reference period is 1 month and, following Eurostat's recommendation, the annual income is the monthly income multiplied by 12, which in the case of irregular income, like that from farming, can bring about considerable distortions. In EU-SILC the reference period is a calendar year preceding the survey;
- Different types of income are taken into account i.e. in HBS the information is collected both about the income in cash and in kind, while in EU-SILC – only about the income in cash (with a few exceptions), which may be important for the income from farming and social benefits other than retirement pay and pension. Moreover, EU-SILC does not take into account the so called lump sums which is the case in HBS;
- Different way of data collection – in HBS the respondents make records in the so called diary. They have to determine the data sources themselves and do not have them listed in the diary. This may cause omissions. In EU-SILC each respondent is asked detailed questions. In EU-SILC all the income missing data are imputed, while there is no imputation in HBS;
- Different way of sample selection – in HBS dwellings in which all the households refused to participate in the survey are replaced with new ones from the so called reserve list;
- Slightly different weighting of results.

In some tables given below the data are presented in the breakdown by socioeconomic group and household size. The household survey results are usually released by CSO in the breakdown by socioeconomic group and household size.

The main criterion for socio-economic group classification is the prevailing source of income. In tables below only weighted data are presented.

**Tab. 1. Structure of population by age**

Specification	EU-SILC 2009	HBS 2009
	in %	
Total	100.0	100.0
0-14	15.5	18.0
15-24	14.6	15.7
25-54	44.0	41.1

Refrigerator	98.5	97.9
Washing machine	97.6	97.9
Passenger car	58.9	57.4

## **4.2. Comparison of Laeken Indicators based on EU-SILC 2008 and EU-SILC 2009**

In 2008 further improvement in the income position of the Polish household, observed since 2004, was maintained. It is due to a relatively favourable situation on the labour market, the unemployment rates showing lower figures than in 2007. Real wages got higher. The real value of retirement pays also increased, although not as much as that of the wages. This was reflected by a further reduction of the poverty range measured with the real poverty line adopted at the at risk of poverty rate anchored at a fixed moment in time for 2005. The income position improvement was also expressed by a reduced economic strain and durables indicator.

In general, no significant changes were noted in 2008 as regards income differentiation. Gini coefficient slightly dropped (from 32.0 in 2007 to 31.4 in 2008), while the income share ratio remained approximately at the same level (5.0 in 2008 as compared with 5.01 in 2007).

Generally speaking, the relative poverty rate estimated for the whole population was approximately at the same level as in 2007 and amounted to about 17% (16.9% in 2007 and 17.1% in 2008), with further increase of poverty among the elderly at 65 years of age or older (from 11.7% in 2007 to 14.4% in 2008). This deterioration of the situation of the elderly in relation to other groups of population is due to a higher increase of wages as compared with retirement pays, which was mentioned above. In 2008 the improvement of the situation of children, noted during the two previous years, was stopped. In relation to 2007 it was possible to note a slight increase in the poverty rate among the population under 18 years of age) from 22.4% to 23.0%).

## **4.3. Comparison between SNA results for the household sector and EU-SILC 2009 (data for 2008) in the scope of incomes**

The comparison covered disposable income and its main components: income from hired employment, self-employment (in and outside farming), as well as social benefits.

It was found out that the disposable income in EU-SILC 2009 made up 64% of the corresponding category in SNA. This was due to the following factors:

1. The household sector in SNA includes collective households which do not enter EU-SILC.
2. Both systems employ different methods of measuring income from self-employment.
3. Accounts of primary and secondary income distribution in SNA used for the determination of disposable income include some items not covered by EU-SILC 2009 or not taken into account in the calculation of its results. The most important of them are imputed rents.

In SNA income from self-employment is determined as the so called operation surplus which is the balance between the global production and current production inputs (i.e. intermediate consumption) and hired employees' wages. This difference is reduced by taxes and increased by subsidies. The operation surplus thus calculated is allocated to the household's consumer needs, housing-related investment as well as production-related investment. In the Polish EU-SILC the question about income from self-employment concerns just the amount allocated to the household's consumer needs and its housing-related investment. In addition, SNA takes into account consumption from own production which is not taken into consideration by EU-SILC for farmers' households. Due to these differences incomes from self-employment according to EU-SILC 2009 made up 30% of the operation surplus only (after deduction of section K).

Incomes from hired employment in EU-SILC 2009 are equal to 101% of the corresponding figure in SNA, while social benefits – 91% respectively, which seems to be a good result.

In SNA incomes of the employees working abroad were calculated in a different way. However, these methodological changes do not explain the increased coherence of incomes from hired employment. The change of weight in EU-SILC could justify an increase by no more than 1 percentage point. The methodological changes of SNA bring about reduced coherence between SNA data and EU-SILC data, since they lead to an increase in wages and other incomes from hired employment in SNA. Considering the fact that SNA data are based on the results of the enterprise surveys, it can be judged that the increased coherence of incomes from hired employment might be due to some deterioration of the quality of enterprise survey results in the scope of wages. Unlike for EU-SILC 2006, 2007 and 2008, it is less probable that the increased coherence of SNA results in the area of hired employment could be brought about by a higher quality of EU-SILC results, as the coherence for all the other significant economic categories remained more or less at the same level.

### Comparison of 2008 results of SNA and EU-SILC 2009 for Poland

Category in SNA	Variables in EU-SILC 2009	Category description in EU-SILC 2009	SNA in mln PLN	EU-SILC in mln PLN	SNA = 100%	SNA = 100% EU-SILC 2009
Gross disposable income (net)	HY020	Total disposable household income (net)	799 085	513 594	64	62
Wages, salaries and other income connected with hired work (gross)	PY010G	Employee cash or near cash income (gross)	426 735	423 255	99	99
Operating surplus (gross) with the exception of section K	PY050G	Self-employment income (gross) - value allocated to household's consumption and dwelling-related investment	226 352	67 485	30	26
Social security benefits and social assistance benefits (gross)	PY90G + PY100G + PY110G + PY120G + PY130G + PY140G + HY050G + HY060G + HY070G	Social benefits (gross)	179 112	163 289	91	93

#### Remarks:

1. Remarks in brackets: "net" or "gross" refer to including or not including income tax and social security contributions, while the word "gross" in SNA names of categories refers to including of depreciation of fixed assets.
2. Data for gross operating surplus in SNA has been taken into consideration with the exception of section K, which allows for better comparability with EU-SILC data on self-employment income (PY050G). The data for section K includes mainly imputed rents, not included in the results of EU-SILC 2009 (data for 2008), and market income from renting of real estate included in EU-SILC as the variable HY040G.
