

**The Consumption of Gambian Households  
in the Integrated Household Survey CSD  
in The Gambia**

Christophe Muller

April 2006

Capacity Building for Economic Management Project (CBEMP)

## Acknowledgement

I am grateful to the CSD and the CBEMP for their support during this mission. I particularly thank the Director of the CSD, Mr. Aliew Ndow, and the Director and the Deputy Director of the CBEMP, Mrs. Fatou Leigh and Mr. Alieu Bittaye for their efficient interventions that contributed to the success of the mission.

I must also acknowledge the quality of the collaboration that I received from the CSD staff associated with the treatment and the analysis of the IHS. Special mention should be done of Lamin Fatty and Abu Camarra who have shown dynamism and very hard work.

Finally, I want to thank Graham Eele and Hoon Soh for their expert remarks and assistance, and the staff of the Departamento de Fundamentos del Análisis Económico of the University of Alicante for their support.

## Executive Summary

This volume presents the statistical results of the IHS survey in the Gambia. The results are presented in three sets: aggregate and mean consumption, consumption composition, and Engel curves.

The estimated levels of consumption are much higher than what was usually assumed for the Gambia in the absence of the type of accurate information that is now provided by the IHS survey. The mean value of consumption is 71,572 Dalasis per year per household. The mean per capita consumption is 8561 Dalasis per year. Consumption levels in Banjul are well above what is observed in the other Local Government Area. Per capita consumption is higher in urban area (6965 Dalasis per year) than in rural area (6925 Dalasis per year).

The structure of consumption of the Gambian household remains dominated by food and beverages that account for about 60 percent of the consumption value when including snacks and prepared meals. Clothing (about 10 percent of the consumption value), Recreation and Culture (8 percent), and Transport and Communications (about 5 percent) are other notable consumption categories that can be identified in these data. In contrast, Health and Education expenses appear as extremely low.

The poorest households have on average a higher food budget share than the other households, and have lower budget shares for transport and communication, and restaurant and hotel expenses.

## **1. Introduction**

The methodology of the analysis is presented in Muller (2006a). This volume presents the estimates of the consumption analysis, accompanied by short comments.

Two previous household consumption surveys had been conducted and analysed by CSD (Central Statistics Department, 1994, Government of the Gambia, June 2000). There also was a small older survey in 1989, of which results have been lost. Moreover, a participatory assessment survey had been carried out just before the integrated survey started (Republic of The Gambia, September 2002 (a,b) and December 2002 (a-e)). Older surveys had been conducted on restricted areas, but the data and the reports have been lost.

A light ‘priority survey’ has also been administered in 1992 (Wadda and Craig, 1993). So, ideally we could make comparisons of poverty with several points in the past: 1989, 1992, 1993 and 1998. In practice, methodology considerations imply that these comparisons are difficult, if not impossible. Finally, household survey results on education and health are available for 1993-94, which can be useful for future comparison with the education and health modules of the IHS (Central Statistics Department, 1995a,b).

There are important differences between the collection design of the IHS and the 1998 survey: (1) the IHS survey is organized over one full year, while the 1998 survey was implemented only over a few weeks; (2) the questionnaire settings of the two surveys are different, suggesting much larger omission errors with the 1998 survey which is

comparatively light. Then, the comparison of the results of the two surveys seems difficult and may be dominated by measurement errors.

## 2. Aggregate consumption

Let us now turn to the new consumption estimates from the IHS survey. The complete results are in Tables A1 to G19. They are organised in nine categories: (A) Aggregate consumption and household consumption means, (B) Consumption per capita, (C) Consumption per quintiles and deciles of per capita real living standards, (D) Consumption per quintiles and deciles of per adult-equivalent real living standards, (E) Mean household consumption composition, level 1, (F) Household consumption composition, level 2, (G) Mean household consumption composition, level 3.

We only comment a few salient features.

The mean value of consumption over the whole country is of **71,572** Dalasis per year per household, with a standard error of D 3,358. The standard error is large, which yields a broad confidence interval: [D 64,990, D 78,153]<sup>1</sup>. The variability in observed consumption due to the limited information period is one reason why the sampling standard errors of consumption estimates in this survey are often quite large for the given sample size. Another reason is the presence of very wealthy households that considerably raises the dispersion of household consumption indicators in this survey, and generate large estimated standard errors.

---

<sup>1</sup> Because we did not incorporate post-strata and pseudo-strata in the calculation of sampling errors, it is likely that the estimate of the confidence interval is slightly larger than what could be obtained with other estimation methods. Note however, that the introduction of small sample corrections for drawing with replacement at both stages of the drawing brought substantial accuracy gains.

The corresponding mean per capita consumption is **8,561** Dalasis per year, with a standard error of 402 Dalasis, yielding the confidence interval [D 7773, D 9348].

For use in macro-economic studies, we also estimated the aggregate consumption value. It is: D **11,020,000,000** per year.

These estimates mean that considerable updating of the perception of the central level of consumption in The Gambia is necessary. To illustrate this point, we now compare these numbers with similar aggregate figures published in the Gambia or in neighbouring Senegal.

The mean consumption estimate per household from the 2003 IHS corresponds to D **5964** per month. In contrast, the preliminary estimates from IHS 2003 were D 2929 per month per household. The preliminary results did not account for own-consumption and consumption from gifts, and underestimated non-food consumption since Part II questionnaire was not available. One issue with the preliminary consumption indicators based on daily diaries only was that the presence of household stocks, in particular for food products, may generate high or low temporary levels of observed consumption, even over a 30 days period. This shortcoming of the daily diaries is now partly compensated by using information from the Part II questionnaire. It also suggests trying to collect information about the presence of stocks in the next survey. Moreover, correcting many mistakes in the files, notably about the variable indicating the collection day, led to a massive increase in the level of consumption estimates. This

should be seen as an encouraging reward for the substantial effort that was devoted to data preparation. The preliminary results can now be dropped.

The results of the 1998 (light) survey, converted into 2003 Dalasis, correspond to a mean consumption of D 3963 per month per household. The results of the 1993 (light) survey, converted into 2003 Dalasis, correspond to a mean consumption of D 3326 (pp 36-37).

These statistics are calculated as follows. The mean total expenditure per person per annum from the 1998 survey was 4073 Dalasis. The household mean size in this survey was about 8 persons per household. Then, we obtain  $4073 \times 8 / 12 = 2715$  Dalasis per household per month in 1998 Dalasi.

To convert this result into 2003 Dalasi, we calculate the Banjul inflation rate between December 1998 and December 2003. We use the Banjul inflation rate since that it is the only available price index for this period. The index in December 1998 is 1497.59. It is 2192 in December 2003. The difference corresponds to an adjustment factor for inflation equal to:  $(2192.21 - 1497.59) / 1497.59 = 0.4638$ . For comparison, the index in January 1998 is 1379.70. It is 1876.44 in January 2003. The difference corresponds to an adjustment factor for inflation equal to:  $(1876.44 - 1379.70) / 1379.70 = 0.3604$ . Then, converting the 1998 results into 2003 Dalasis gives:  $2715 \times 1.46 = 3963$  Dalasis using December price index, and  $2715 \times 1.36 = 3692$  Dalasis using January index.

Similarly for comparing with 1993, we use the published results for the mean permanent income per person per year: 5462 Dalasis and mean household size of 8.7

members. Then, the mean permanent income per household = 3960 Dalasis (in July 1993 Dalasis) =  $3960 \times 1.5488 = 6133.24$  (in June 2003 Dalasis). Note that in 1993 there was a drought before the survey. It reduces the consumption levels of households as compared to a normal year.

Although some readers may want to interpret the difference of these figures with the IHS survey as evidence that consumption per household has dramatically increased since 1993 and 1998, we believe that a more likely explanation is that the surveys in 1993 and 1998 were affected by larger measurement errors, and in particular larger omissions than the IHS. Indeed, the large difference in collection and treatment methods across these surveys imply that the direct comparison of economic estimates from these surveys is probably meaningless and should not be done except for checking possible errors. Here, the comparison may merely tells us that the IHS is probably not affected as much by omission errors than the past surveys.

CSD has published the 2003 GDP at factor prices: D 2855 per month per household. Besides, the 2003 agricultural output in The Gambia is assessed at D 1262 per month per household by the Ministry of Agriculture of The Gambia. Here, comparing with the IHS estimates for per household consumption, which is only a part of the GDP, suggests that massive revisions in the aggregate statistics of the Gambia are necessary.

Finally, using the 1994/95 survey for Senegal and the exchange rate between the Dalasi and the CFA leads to a mean household consumption in Senegal with a value, converted to 2003 Dalasis, of between D 3281 to D 2787 (depending if one starts the calculus from published aggregate consumption or from per capita consumption). The calculus is

as follows. From the Senegal publications we obtain a mean expenditure per household of 1,494,852 CFA and a mean expenditure per capita of 147,495 CFA. Correcting for the inflation from December 1994 to December 2003 gives:  $(94/5000)/12 \times (1876.44 - 1339.4)/1339.4 = 3282$  Dalasis.

As the Senegalese survey is known to have met serious collection difficulties, it does not seem surprising that the better accuracy of the Gambian IHS survey produces higher estimates of mean consumption. The comparison with the 2001 Senegalese survey is difficult because the collection of this survey stopped after four months, and extrapolation to a full year are doubtful.

Let us now turn to aggregate consumption estimates by geographical divisions. The mean annual consumption in the urban part of the country is estimated at D 77,363 (Standard error 4,322) per year per household, lower than in rural areas where it is D 67,080 (4,932) per year per household. When converted in per capita figures these numbers correspond to a mean annual consumption per capita of **D 11,637** (636) in Urban area, and of **D 6,925** (486) in Rural area. Then, the relative proximity of household means between Urban and Rural area correspond to much lower consumption per capita in Rural area. This is due to the larger mean household size in the countryside.

One could wonder if accurate estimates of mean consumption can be produced at the LGA-Rural/Urban (i.e. Strata) disaggregated levels, despite the more limited sample size for these sub-populations. The following table shows that this is hardly possible. The sample size in each stratum is small and consequently the standard errors (shown in

(parentheses) are large when focusing on strata. Moreover, the presence of a few wealthy surveyed households in some strata, as in Mansakonko rural, strongly reduces the accuracy of the mean estimates. The calculation of confidence intervals from standard error is presented in Muller (2006a).

Per capita annual consumption:

|                    | Mean   | Standard error |
|--------------------|--------|----------------|
| Banjul Urban       | 23,656 | (1,713)        |
| Kanifing Urban     | 11,450 | (898)          |
| Brikama Urban      | 8,503  | (939)          |
| Brikama Rural      | 8,850  | (875)          |
| Mansakonko Urban   | 5,806  | (1,176 )       |
| Mansakonko Rural   | 9,007  | (3,228 )       |
| Kerewan Urban      | 7,567  | (1,413 )       |
| Kerewan Rural      | 5,796  | (1,138)        |
| Kuntaur Urban      | 5,302  | (279)          |
| Kuntaur Rural      | 3,026  | (265)          |
| Janjangbureh Urban | 6,665  | (1,883)        |
| Janjangbureh Rural | 5,030  | (455)          |
| Basse Urban        | 9,425  | (1,314)        |
| Basse Rural        | 6,114  | (1,317)        |

A few robust elements still emerge. First, the mean per capita consumption level in Banjul is without doubt well above the levels obtained in the other strata. This is also

the case for Kanifing, while to a much smaller extent. On the other side of the spectrum, Kuntaur rural is characterised by very low mean per capita consumption. The other strata are more homogeneous as a group and they can be regularly ranked using their per capita consumption mean from the lowest Jangjangbureh Rural to the highest Basse Urban.

However, the comparison of this group of strata is made delicate by the large estimated standard errors for these statistics. More than a precise ranking of strata, rigorous statistical tests at usual confidence levels show that many of the estimated means of per capital annual consumption are not significantly different across strata. Larger sample sizes would be necessary to reach safer conclusions on this issue of comparison of consumption levels across strata. We already mentioned that one reason for this situation is the presence of very rich households in most of the strata of the country, which contributes to raise the dispersion statistics, among them the estimated standard errors. This issue is also present when comparing household consumption means, living standard means, and inequality estimates. A response to the difficulty of comparing strata or LGA in this survey would be the implementation of a poverty map, which is possible with the recent availability of census data for dates very close to that of the IHS survey implementation. Another possibility is to estimate consumption mean for only part of the household population, excluding very rich households. The next section deals with estimation of consumption across categories of products.

### **3. Consumption composition**

Tables E1 to G19 show the estimates of consumption composition statistics.

Serious problems arose about the coding of product names in the questionnaires during the collection and the data entry. Notably, no nomenclature of products was used during the collection, and product names were freely entered by hand by the enumerators. These difficulties much limit the product nomenclatures that can be used for the analysis. However, after tedious examination of the data we were able to regroup consumption in three levels of product categories. The first level summarizes the large traits of the consumption composition at aggregate level in a fashion consistent with typical international nomenclatures used for national accounts. The second level of consumption categories allows us to decompose food consumption into more disaggregate categories that better elicit the nature of the consumed products. Finally, the third level of the consumption categories allows us to exhibit information about the few homogenous products that can be identified in the codes of the collection nomenclature. The codes and description of the nomenclature of analysis are provided in the appendix. More statistics could be produced in the future by using other ways of disaggregating the collection nomenclature.

Food largely dominates the consumption of the Gambian households. Not only direct food purchases, own-consumption and received gifts amount to a mean consumption share close to half the total consumption (47.5 percent complemented by 0.5 percent of consumption of mostly alcoholic beverages and tobacco), but also 13.2 percent of total

consumption stems from expenses made in restaurant, hotel and other catering establishments. Most of the latter expenses seem to correspond to snacks and prepared meals that can be assimilated to food consumption. Then, the total share of food consumption is probably about sixty percent, at most 61.2 percent. Such a proportion is typical of countries at the stage of development of The Gambia. These figures can be seen as a confirmation of the quality of the data of the IHS survey.

Beyond food, two categories of products represent important parts of total consumption: Clothing (9.7 percent) and expenditure for Recreation and Culture (7.8 percent). Some of these expenses are partly associated to schooling of the children in The Gambia, notably expenses associated with school uniforms and school books and material. This explains why the percentage of the education expenditure is small (1.1 percent). This small percentage mostly corresponds to education fees.

Transport and Communication consumption amounts to 5.1 percent of total consumption. Many of these expenses are related to daily commuting of the Gambian workers between their home and their workplace, some of them traveling large distances every day.

Expenditure related to housing, water and energy are limited with only 4.2 percent. One reason of this small share may be the inclusion of imputed rents in these statistics. Indeed, in the context of The Gambia, it is not possible to realistically extrapolate the few records of rent transactions, mostly in the urban areas, to the accommodation conditions of most Gambian households, and certainly not in the rural areas where no rent market exist in general. This is a normal practice not to attempt to impute virtual

rents in the case of developing economies similar to The Gambia and we follow such sound routine. This convention has little importance for consumption statistics as soon as the definition of consumption is well understood as including actually observed rent transactions and excluding imputed rents.

However, one must be aware that mean living standards in rural areas will be underestimated when compared with urban mean living standards with this rule. Fortunately, this has little consequence for poverty analyses since rents are generally paid by non-poor households.

The expenses for household equipment reach 4.1 percent of the total consumption value. This is consistent with the reduced stock of equipment and furniture commonly observed in Gambian houses.

Health expenditure is very low, at 1 percent of total consumption. One element of explanation of this small proportion is that many health treatments in The Gambia are subsidized or even free of charge. Nonetheless, such low level of health expenditure is worrying considering the acuity of health problems affecting the Gambian households. Indeed, infant mortality is 91 per thousand, while life expectation at birth is only of 52 years.

Finally, miscellaneous expenses have been regrouped in a category that represents 5.6 percent of total consumption. This category notably includes expenditure for personal care. However, it is often hard to separate clearly defined expenses in some records of this category.

## 4. Engel Curves

Another perspective on the consumption structure is provided by the Engel curves presented in Figures 13 to 23. On these graphs each dot represents for a given household: (1) the budget share of a given category (e.g. Food for Figure 13), and (2) the level of per capita consumption. The obtained set of dots is summarized by the shown correlation curve of the budget share as a function of per capita consumption, estimated non-parametrically. The curve indicates how the budget share changes when per capita consumption increases and the influence of other factors are neglected. As few households are observed over a consumption level of 20,000 Dalasis per capita per year, it is better to focus the attention on the left-hand-side part of the graphs that are estimated more accurately. Also, the extreme left of the curves graphs correspond only to a few observed households and should be discarded.

What generally emerges from these estimates is a remarkable regularity of the budget shares over the per capita consumption distribution. However, as expected, the poorest households (in terms of nominal per capita consumption) have on average a higher Food share than other households, and lower budget shares for Transport and Communication, and Restaurant and Hotel expenses.
