

REPUBLIC OF RWANDA

NATIONAL INSTITUTE OF STATISTICS OF RWANDA

EICV₃ THEMATIC REPORT

Environment and Natural Resources

August 2012

Foreword

The 2010/11 Integrated Household Living Conditions Survey, EICV3 (Enquête Intégrale sur les Conditions de Vie des Ménages), is the third in the series of surveys which started in 2000/01 and is designed to monitor poverty and living conditions. The survey fieldwork commenced in November 2010 and continued for one full year. In 2010/11, for the first time the achieved sample size of 14,308 households in the EICV3 was sufficient to provide estimates which are reliable at the level of the district.

To date, two publications have been issued by the National Institute of Statistics of Rwanda (NISR) using EICV3 data: a report with an overview of main indicators and a poverty profile. The present report is one of a series of 10 further documents that each explores in depth a theme from the Economic Development and Poverty Reduction Strategy (EDPRS) using data from EICV3 and a limited number of other sources. The objective is to provide analysis that will contribute to the understanding of the sector and to support the elaboration of Rwanda's Second EDPRS.

The 10 thematic reports in this series are: (i) Economic Activity; (ii) Utilities and Amenities (water/sanitation/energy/housing/transport/ICT); (iii) Social Protection; (iv) Environment and Natural Resources; (v) Consumption; (vi) Gender; (vii) Youth; (viii) Education; (ix) Agriculture; and (x) Income.

This report also draws on information contained in the Labour Market and Economic Trends in Rwanda report from August 2007, which reported on the EICV2 survey, and the Establishment Census of 2011. The report also includes some text from the Main Indicators Report of the EICV3 and makes some revisions to the data published there as a result of deeper analysis of the data.

Yusuf MURANGWA

Director General

National Institute of Statistics of Rwanda

Acknowledgements

This report has been prepared with participation of a large number of individuals and organizations. We would like to express our gratitude to all of them.

We would like to express our sincere appreciation to the partner Ministries, Institutions, agencies and development partners for their respective great support and inputs throughout the process of writing and publishing this report.

We also express our profound gratitude to the team of Oxford Policy Management (OPM), and in particular to Mary Strode and her colleagues. Their technical assistance contributed to the success of this report.

We also thank the technical staff from National Institute of Statistics of Rwanda (NISR) for their unfailing participation in all activities of the survey data analysis, which was coordinated by HABIMANA Dominique and his assistants, APPEL Derek and KARANGWA John.

We appreciate the valuable support provided by administrative and financial departments of the NISR. Their interventions allowed this survey data analysis to be carried out smoothly and under good conditions.

Methodological notes for readers

Urban and rural classification in the EICV3 data

Although the sampling frame for the EICV3 was based on an updated frame of villages, the urban and rural classification of the villages in the EICV3 data is based on the corresponding geographic designations from the 2002 Rwanda Census of Population and Housing. Since the EICV2 sample design was based on the sampling frame from the 2002 census, this urban/rural classification in the EICV3 data makes it possible to directly compare the urban and rural results from the EICV2 and EICV3 data. However, the urban/rural codes in the EICV3 data do not represent the current status of these villages, so it is important that users understand how to interpret the urban and rural results from the data. For example, since the urban classification was mapped directly from the 2002 geographic structure of Rwanda, the estimated total urban population from the survey data will not represent the expected urban expansion of the population. It is even possible that the estimate of the percentage of the population that is urban from the EICV3 data is slightly less than that from the EICV2 data because of sampling variability.

The initial urban/rural classification of the villages in the EICV3 sampling frame was determined at the level of the old sectors. In the 2002 Rwanda census frame, 1,545 sectors were defined for Rwanda. Under the new geographic structure these were reconfigured into 416 new sectors. Each of the 2002 sectors was classified as either urban or rural, and all the zones de dénombrement within the sector were given the corresponding urban/rural code. A spreadsheet was compiled showing the geographic correspondence between the 2002 sectors and the current sectors. When all the old sectors corresponding to a new sector were either urban or rural, the corresponding classification was assigned to all the villages in this sector. However, in the case of new sectors that are composed of both urban and rural old sectors, the villages were assigned a code of 3 for 'mixed'. The EICV3 sampling frame of villages for each district was ordered by urban, mixed and rural classifications in order to provide implicit stratification and a proportional allocation of the sample to each of these groups. For EICV3, there were 106 sample villages in new sectors classified as mixed, for which it was necessary to have a special cartographic operation to determine the urban/rural classification. The file with the GPS coordinates of each EICV3 sample village was used to pinpoint the exact old sector where the village was located. In this way it was possible to obtain the 2002 urban/rural classification for all the villages in the EICV3 sample.

The NISR is currently updating the urban and rural classification of all villages in preparation for the 2012 Rwanda census. Once these urban/rural codes have been finalised, it will be possible to merge these codes into the EICV3 data file so that the sample can be post-stratified and tabulated by the current urban and rural classification. This will not affect the weights in the survey data, which are based on the probabilities of selection. It is important to tabulate the urban and rural results using the new codes in order to represent the current distribution of the population and their characteristics (for the reference period of EICV3). However, the 2002 urban/rural codes should also be kept in the EICV3 data file for comparing the results to EICV2.

Confidence intervals at the provincial urban/rural level

Readers should be aware that the urban component of the rural provinces is very small, as is the rural component of Kigali City. Estimates presented for these urban and rural domains are consequentially affected by large sampling errors.

Readers are recommended to check carefully the sampling errors presented in the annexes.

The tables below show the unweighted sample sizes at provincial level for urban and rural domains.

EICV3	Urban/rural 2002		Total (000s)
	Urban (000s)	Rural (000s)	
Kigali City	1,177	171	1,348
Southern Province	492	3,348	3,840
Western Province	204	3,156	3,360
Northern Province	132	2,268	2,400
Eastern Province	144	3,216	3,360
Total	2,149	12,159	14,308

EICV2	Urban/rural 2002		Total (000s)
	Urban (000s)	Rural (000s)	
Kigali City	954	72	1,026
Southern Province	279	1,428	1,707
Western Province	153	1,500	1,653
Northern Province	135	924	1,059
Eastern Province	99	1,356	1,455
Total	1,620	5,280	6,900

Quintiles and poverty classifications

The results are presented by quintile. Quintiles are developed by sorting the sample of households by annual consumption values, and then dividing the population into five equal shares. The 20% of individuals with the highest annual consumption are allocated to quintile 5, and the 20% of individuals with the lowest levels of annual consumption are allocated to quintile 1. The poorest households and their members are found in quintile 1 and the richest are found in quintile 5. Those around the poverty line are found in quintile 3.

Consumption is used as a proxy for income, as is usual when estimating poverty. The reader should refer to the report on the Evolution of Poverty in Rwanda from 2000 to 2011 for further information on this topic.

Executive summary

On 7 February 2012, the President of Rwanda officially launched the design phase of the EDPRS2. A key input into the development of the EDPRS2 is the evidence collected through the EICV3, fieldwork for which was carried out by the NISR between November 2010 and November 2011. The NISR will release a series of 10 reports that explore in depth 10 different topics that are of high importance to the elaboration of EDPRS2.

This report is one of these 10 thematic reports that seek to inform and support the development of the EDPRS2 with data from the EICV3. It focuses on the environment and natural resources sector, providing detailed insights into the living conditions of the Rwandan population with regard to these themes.

This report explores a wealth of evidence collected through the EICV3 and complements it with further data sources (e.g. EICV2 and sector documents) in order to put this new evidence into a meaningful context. It also makes use of the fact that the EICV in its third round achieved for the first time a sample size that is sufficient to provide estimates that are reliable at the level of the district.

The report discusses first the interactions between a growing population in Rwanda and their human settlements with the environment. It then presents information on the natural resources that allow Rwandan households to maintain and develop their standard of living. Finally, it discusses potential threats resulting from the environment and its deterioration.

Population growth and the environment

Rwanda has a fast-growing population which totalled almost 11 million people in 2011. There is no question that population growth can contribute to environmental degradation, because it puts increased pressure on the assimilative capacity of the environment. The population of Rwanda is projected to increase to almost 14 million people by 2020. In addition to the overall population growth, population density is a crucial indicator in relation to the environment. This is especially true in the case of Rwanda, which is one of the most densely populated countries both in Africa and the world. The current density levels are already regarded as a major driver of internal migration as well as stress to the physical environment, and density is bound to further increase. However, fertility declined strongly in Rwanda in recent years.

Population growth can contribute to environmental degradation. However, these effects can be mitigated through modern technologies or awareness programmes. 97% of households stated they received some sort of environmental information, and meetings as well as radio broadcasts were the main means of receiving such information.

Human settlement and waste management

The impact of humans on environmental degradation can be mitigated by modern technologies (e.g. integrated pest management in agriculture or recycling/composting in waste management), but equally so by simple behavioural patterns such as the proper treatment of waste or use of sustainable fuels. Traditionally, rural habitat in Rwanda has been made up of scattered and isolated dwellings. Such settlements make it difficult to develop accessible rural infrastructure and provide basic services for sustainable use of natural resources and treatment of the environment. However, the data show a clear trend away from the traditional isolated habitat towards *imidugudu* or other clustered forms of habitat.

The trend towards modern and clustered settlements, in combination with labour migration and other factors, has led to a very high degree of mobility among the Rwandan population over the last few years. Almost half of Kigali residents have only lived in their current dwelling for less than five years, and even in other provinces many households have only moved into their current dwelling in the past five years. Nevertheless, despite these strong changes in habitat, isolated rural dwellings are still the most common form of housing for the poorest quintile.

Households that live in modern or planned settlements tend to be provided with better management of waste and sewage. The trends in habitat type are thus accompanied by improvements in waste management. In urban areas, provision of refuse collection services has increased from 23 to 30%, and use of compost heaps has increased in rural areas from 60 to 64%. These are, however, modest changes and indicate that sustainable waste management is still not a priority for many households.

In addition to solid waste management discussed above, the disposal of liquid wastes through improved sanitation facilities is also an important factor in preventing environmental damage. The percentage of households with access to improved sanitation has increased considerably over the past five years in Rwanda, from 59 to 75%.

Considerable improvements can also be observed in construction materials used for dwellings, e.g. the increase in households with cement floors (13 to 17%), the growing trend of using bricks for walls rather than tree trunks (households using bricks increased from 45 to 57%), or the switching from thatched roofs to metal sheets (metal sheet usage increased from 44 to 54%).

Energy resources

Use of fuels can be a major strain on the environment. On the other hand, fuels are an essential day-to-day environmental resource allowing Rwandan households to maintain and improve their standard of living. Hence, a balance must be found between an energy supply that ensures economic development but makes sustainable use of natural resources in the long run.

Firewood is still the fuel used for cooking by the vast majority of the rural population (93%). In the cities, charcoal is used by 51% of households, followed by firewood (45%). While rural households have not changed the fuels they use for cooking in the last five years, a slow trend can be observed in the cities away from firewood and toward charcoal.

The percentage of households connected to electricity has increased substantially over the last five years, especially in the cities (23 to 46%). Overall, it changed from 4 to 11%. 'Green' energy sources such as solar power or biogas play a negligible role in household energy use in Rwanda.

Private ownership of motorised vehicles is another source of demand for fuels, but this is still very low in Rwanda. Commercial/industrial use of fuels constitutes a further source of energy demand, and this is sure to increase in the coming years.

Water resources

In addition to energy, another essential natural resource for human survival and development is water. In general, access to safe drinking water has a direct impact on the population's quality of life, health, and productivity.

Access to improved drinking water sources has increased in Rwanda, from 70 to 74%. Kigali City has the largest percentage of households using an improved drinking water source (83%) with 33% having water piped into their premises. The proportion of households using surface water

(rivers or lakes) as drinking water has decreased from 18 to 12%. Rural households can now reach an improved water source more quickly than they could five years ago.

Expenditure on water constitutes only a negligible proportion of household expenditure (less than 1%). However, there is a clear trend that fewer households receive their water for free when compared to five years earlier (from 81 to 69%).

Land management and agricultural practices

Land is one of the three main factors of production and its finite nature makes it a very valuable natural resource. Use and management need to be carried out in a sustainable and rational manner. Given a growing population combined with strong reliance on agriculture, land is one of the scarcest natural resources in Rwanda.

The average area cultivated per rural household is only 0.6ha. The Food and Agriculture Organisation of the United Nations (FAO) estimates that on average a Rwandan household requires at least 0.9ha to conduct sustainable agriculture. However, only 17% of rural households cultivate 0.9ha or more in Rwanda. The majority of cultivating households across all provinces have less than 0.9ha (83%), or even less than 0.3ha (46%).

With a growing population, land is becoming even scarcer over time. The average size of land cultivated per rural household has decreased in five years in all provinces except the Southern Province, where it was already lowest out of all provinces five years ago. The changes observed are: Western Province 0.6 to 0.5ha; Northern Province 0.9 to 0.5ha; and Eastern Province 1.0 to 0.8ha; Southern Province 0.6 to 0.6ha. This could suggest that the Southern Province has already reached the point at which no further land sharing is possible. In provinces other than the Southern Province, land cultivated per household has reduced between surveys, but it is now on average around 0.5ha across all provinces except Eastern Province, and this is approximately the level at which no further reduction was observed in the Southern Province over the last five years. If the assumption holds that below this level no further land sharing is possible, Rwanda might see a lot more young individuals without access to land in the Southern, Western and Northern provinces in the coming years.

One of the strategic objectives of the land sub-sector is to ensure security of land tenure. The EICV provides information on both land ownership and exposure to the Land Tenure Regularisation (LTR) process. The dynamics of land ownership changed quite considerably over the period 2005/06 to 2010/11, with ownership models diversifying and an increase in land transactions on the land market. 54% of households had been exposed to the LTR in 2010/11, and most of those were at the stage of either having a claims receipt issued or having their land registered.

84% of cultivating households have the right to sell their land or use it as a guarantee for a loan. Comparison with five years earlier shows that the proportion of households that can sell their land or use it as a guarantee has increased substantially. Among households that accessed a formal source of credit, 34% used land as collateral to obtain the loan.

Use of chemical fertiliser has increased strongly from 11 to 29%. The land area under irrigation is currently at 3%. The push towards erosion control has been successful. 78% of land is protected against soil erosion.

Economic dimension of the environment and natural resources sector

The impact of the environmental sector on economic growth is difficult to assess given that linkages are usually indirect. It is safe to say that without the environment and natural resources, no economic development would be possible.

72% of working individuals above the age of 16 have their main job in agriculture. This clearly shows that the natural resource of land is an important factor in the country's economy, and this is especially true in the rural areas, where agriculture provides main jobs for 78% of the working population.

There are further sectors relating to natural resources which provide jobs for the Rwandan population, which are tourism, forestry and mining. The proportions of working individuals with main jobs in the forestry and mining sectors are very small, however, and currently these sectors do not constitute major drivers of job creation in Rwanda.

Human health and the environment

As with the economic growth, the link between the environment and health is difficult to capture through official statistics since the link is not direct and often not measurable. A general overview of correlations between environment-related indicators and health complaints suggests that health problems are higher among people that use non-improved sanitation and also slightly higher among those using non-improved drinking water sources. Likewise, people using firewood have a higher incidence of health problems compared to others. However, it is important to note that this does in no way imply causality.

Data on different diseases in Rwanda are also presented. These data focus on diarrhoea, respiratory infections and malaria, all of which can be caused by unfavourable environmental conditions such as unhygienic water, air pollution, or infested swamps.

Major problems related to the environment

Sometimes the environment can also be a major source of destruction, such as through floods or destructive rains. 44% of households in Rwanda have experienced some sort of impact due to environmental disasters. Most of these relate to reduction in harvests, either directly or through erosion, loss of soil fertility, destructive rains or droughts. As expected, rural households (which rely heavily on natural resources) are more vulnerable to environment-related disasters than urban households.

1 Introduction

On 7 February 2012, the President of Rwanda officially launched the elaboration of the EDPRS2. At the same time, the first EDPRS entered its final year of implementation 2012/13.

A key input into the elaboration of the EDPRS2 is the evidence collected through the EICV3, fieldwork for which was carried out by the NISR between November 2010 and November 2011. Two reports based on EICV3 data were released by the NISR in early 2011, a main indicators report and a report on poverty evolution in Rwanda. Following on from these initial publications, the NISR will release a series of 10 further reports that explore in depth 10 different topics that are of high importance to the elaboration of EDPRS2.

This report is one of these 10 thematic reports that seek to inform and support the development of the EDPRS2 with data from the EICV3. It focuses on the environment and natural resources sector. As mentioned in the environment sector's EDPRS self-assessment report, key environmental indicators were integrated for the first time in the EICV3.

This report explores a wealth of evidence collected through the EICV3 and complements it with further data sources (e.g. EICV2 and sector documents) in order to put this new evidence into a meaningful context. It also makes use of the fact that the EICV in its third round achieved for the first time a sample size that is sufficient to provide estimates that are reliable at the level of the district.

Following some short methodological notes in the following section, chapters 3 and 4 of this report discuss the interactions between a growing population in Rwanda and their human settlements with the environment. Chapters 5, 6, 7 and 8 present information on the natural resources that allow Rwandan households to maintain and develop their standard of living. Finally, chapters 9 and 10 discuss potential threats resulting from the environment and its deterioration. The annexes provide district-level estimates for selected indicators as well as confidence intervals.

2 Indicatorselection, data sourcesand data gaps

The data available on environment and natural resources in Rwanda are manifold as well as fragmented. Given the cross-cutting nature of most environmental issues, the relevant data cover themes as far-reaching as agriculture, health, labour, exports, etc. As a result, the sector's monitoring and evaluation (M&E) framework includes a very large number of progress indicators, covering many different topics.

The overall achievements of the sector in regard to the EDPRS targets are monitored by a selection of four indicators in the EDPRS Results and Policy Matrix and two indicators from the Common Performance Assessment Framework. The Environment Joint Sector Review Report 2010/11 summarises achievements against these indicators as follows:

Table 2.1 Sector achievements against EDPRS/CPAF performance indicators

Indicator	Targets 2010/11	Actual performance
Proportion of registered privately owned land having women as owners or co-owners	50%	84%
% of watersheds with known water quantity	10%	7%
% of national forest cover	22.1%	22.1%
Total revenue from exports of mineral products (in million USD)	89	116.8
Number of land titles issued	3,024,000	6,380,033
Area of land protected to maintain biological diversity	9.2%	10.13%

Source: Environment and Natural Resources Joint Sector Review Report 2010/11.

The amount of sector M&E indicators and their cross-cutting nature constitute an unusually high demand for data from a wide range of sources. For some sector performance indicators, there are still gaps in availability of data. The NISR has worked closely with sector stakeholders during the planning phase of the EICV3 to ensure that, where possible, key sector indicators are included in the EICV3 questionnaire. Likewise, the preparation of this report was carried out in close collaboration with sector M&E officers. With their help, a list of indicators was selected that can be provided from NISR sources in order to support the sector in the arrangements for EDPRS2.

This report covers these selected sector performance indicators using mainly EICV3 data, but also further NISR sources. For example, EICV2 data is often used to put indicators into context and to assess trends over time. District estimates from EICV3 are provided in Annex A. In addition, this report refers to other official data sources wherever this is helpful in order to validate and compare the EICV3 estimates with other information, or to discuss issues further where the scope of EICV data ends.

It must be clear, however, that this report cannot cover all of the manifold M&E indicators of the environment and natural resources sector. Given that the EICV is a household-level survey, there are clear limitations in the questions it can answer and the information it can provide. Sometimes, sector indicators that are not at the household level and therefore not available from EICV can instead be covered by data sources from implementing ministries and agencies. However, in other cases no data currently exist and would require specialised surveys. In a few remaining cases, the sector has expressed interest in household-level information that could be included in future EICV surveys (e.g. rain-water harvesting practices or use of improved cooking stoves) and this will be considered by the NISR in the development of the next EICV. Further data gaps with regard to the sector performance targets are discussed in the relevant chapters.

3 Population growth and the environment

Rwanda has a fast-growing population which totalled almost 11 million people in 2011. There is no question that population growth can contribute to environmental degradation, because it puts increased pressure on the assimilative capacity of the environment.¹ These effects can, of course, be mitigated through modern technologies or citizen awareness programmes. However, understanding population growth and surrounding topics are an important starting point when thinking about Rwanda and the state of its environment.

The population of Rwanda is projected to increase to almost 14 million people by 2020 as the medium-level projections in Table 3.1 make clear. However, it is important to note that these projections are based on the last census and revised projections are likely to be developed after the coming census.

Table 3.1 Population projections

Year	Medium projection			Low projection			High projection		
	Total	Male	Female	Total	Male	Female	Total	Male	Female

In addition to the overall population growth, population density is a crucial indicator in relation to the environment. This is especially true in the case of Rwanda, which is one of the most densely populated countries both in Africa and the world. The growing strain on natural resources, especially land, is illustrated in Table 3.2 below. As the population of Rwanda grows, a projected 525 persons will on average be sharing a square kilometre of the country. The current density levels are already regarded as a major driver of internal migration as well as stress to the physical environment² and density is sure to further increase. (A more detailed assessment of the scarcity of lands in Rwanda can be found in Chapter 7.)

¹ For an interesting introduction to the scientific debate on the interactions between population growth and environmental degradation, see Cropper/Griffiths (1994), 'The Interaction of Population Growth and Environmental Quality' in *The American Economic Review*, Vol. 84, No. 2, pp. 250–254.

Population growth and fertility rates are inseparably linked. Table 3.3 shows that the highest fertility rates in 2010 were found in the Western Province as well as the poorer quintiles (5.4 children per woman in quintile 1). Women with no education had the highest fertility rates.

Table 3.3 Current fertility rate

Despite differences in fertility across regions and income groups, it is important to note that fertility has declined strongly in Rwanda in recent years. As shown in Table 3.4, fertility during the period 2000–2008 remained relatively stable but it has declined considerably since, in 2010 reaching 4.6 children per woman. The RDHS also shows that fertility rates are declining for all women, irrespective of location or income; however, the decline is strongest in the Northern Province and wealthier households.

Table 3.4 Trends in fertility

Source: RDHS 2010. Note: Note: Age-specific fertility rates are per 1,000 women. The RDHS employs women's birth histories to calculate fertility rates.

As mentioned earlier, population growth can contribute to environmental degradation. However, these effects can be mitigated through modern technologies or awareness programmes. It is very difficult to measure the population's level of awareness with regard to environmental degradation and protection, given that awareness is not easily quantified. The EICV3 did, however, ask respondents whether they received any information on environmental issues from various sources. 97% of households stated they did, and meetings as well as radio broadcasts were the main means of receiving such information. The lowest rates of exposure in rural areas are found in the Western Province. Households with lower incomes also tend to be less informed about environmental issues compared to richer households.

Unfortunately, the quality of the information received is not measured and the data cannot assess whether or how the environmental information disseminated among Rwandan households helps to mitigate the negative effects of humans on the environment.

In the light of this data, it might be helpful to know that radio broadcasts appear to be a cost-effective and inclusive way of disseminating information to the population. As shown in Table 3.6 below, radio ownership is now at 60% of households in Rwanda, and it differs strongly from other ICT devices in that ownership is not limited to the urban rich. 61% of rural households now own a radio, and this is still true for 43% of the poorest households. Making further use of radios to increase the population's awareness of environmental degradation and protection seems advisable. Of course, the information and recommendations made available need to be presented in a format that is digestible and directly applicable by even the uneducated parts of the population.

4 Human settlement and waste management

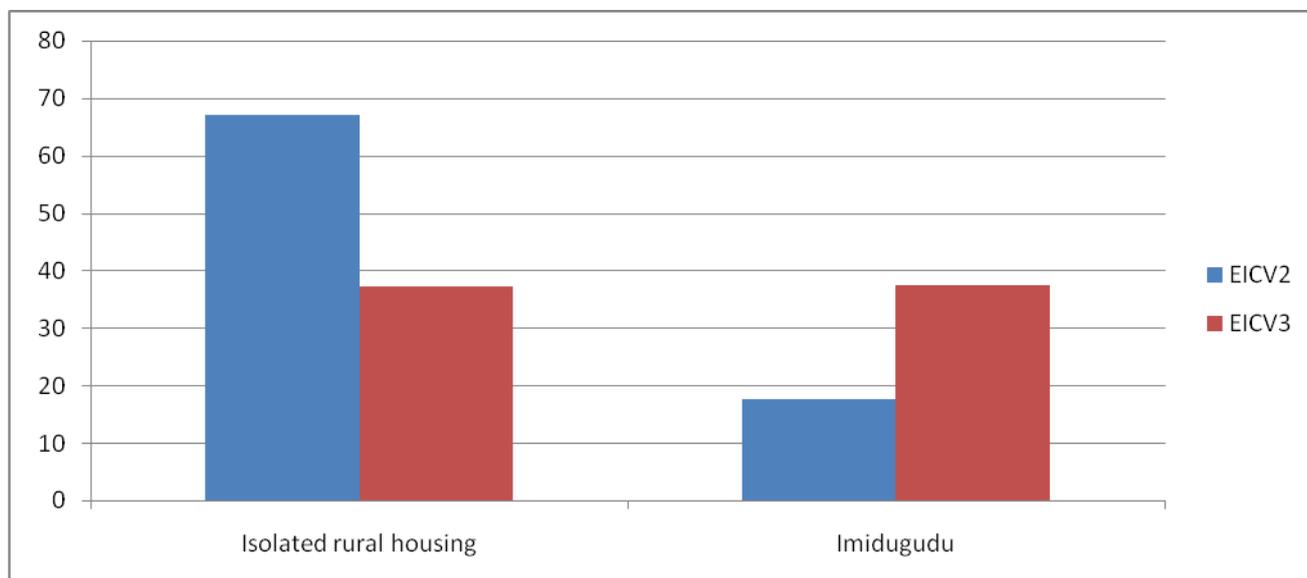

The impact of humans on environmental degradation can be mitigated by modern technologies, but equally so by simple behavioural patterns such as the proper treatment of waste or use of sustainable fuels. This chapter and the following two discuss behavioural patterns observed in Rwanda that relate to settlement and construction, waste management, use of fuels and water access.

Traditionally, rural habitat in Rwanda has been made up of scattered and isolated dwellings. Such settlements make it difficult to develop accessible rural infrastructure and provide basic services for sustainable use of natural resources and treatment of the environment. In addition, recent years have seen the emergence of unplanned residential areas in urban centres, which mostly display a strong lack of infrastructural planning. Furthermore, the aftermath of the genocide required interventions in human settlements including ad hoc construction of camps or temporary housing schemes.

All these factors complicate the development of environmentally sustainable forms of human settlement. One example is the fact that Kigali has no system of sewers or a central treatment facility for sewage.³ Likewise, rubbish collection services reach less than half of urban households.

However, the data shows a clear trend away from the traditional isolated habitat towards *Imidugudu* or other clustered forms of habitat, which is in line with national policy. Figure 4.1 (and Table 4.1 later) show that the proportion of households living in isolated rural dwellings has decreased strongly between 2005/06 and 2010/11.

Figure 4.1 Change in specific habitat types

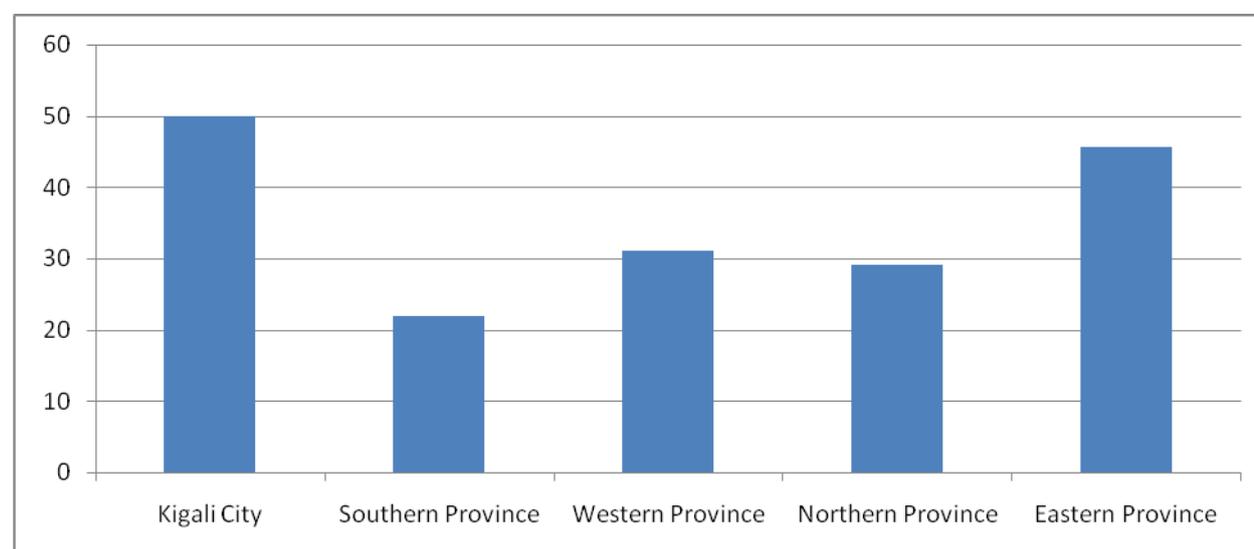

Source: EICV3 and EICV2.

The trend towards modern and clustered settlements, in combination with labour migration and other factors, has led to a very high degree of mobility among the Rwandan population over the last

³ Rwanda State of Environment and Outlook, REMA/UNEP, 2009.

few years. This is illustrated in Figure 4.2, which shows that almost half of Kigali residents have only lived in their current dwelling for less than five years.

Figure 4.2 % of HHs that have lived less than five years in their current dwelling

So

Source: EICV3.

Despite these pronounced changes in habitat, isolated rural dwellings are still the most common form of housing for the poorest quintile (51%) and especially in the rural Southern Province (57%).

Source: EICV2.

Households that live in modern or planned settlements tend to be provided with better management of waste and sewage. The trends in habitat type are thus accompanied by improvements in waste management, as can be seen in Figure 4.3 and Table 4.2. However, it should be noted that the improvements are not as pronounced as one might expect. In urban areas, provision of refuse collection services has increased from 23 to 30%, and use of compost heaps has increased in rural areas from 60 to 64%. The use of publicly managed refuse areas decreased between EICV2 and EICV3, which can likely be explained by urban households now benefitting from rubbish collection services and therefore no longer using the publicly managed refuse areas as their main mode of rubbish disposal.

These are modest changes and indicate that waste management is still not a priority for many households. As subsequent tables on construction materials will show, Rwandan households have strongly improved their dwellings over the past five years, a development that could be mirrored more closely in waste management behaviour.

In addition to solid waste management discussed above, the disposal of liquid wastes through improved sanitation facilities is also an important factor in preventing environmental damage. Deep pit latrines can have a hazardous impact on ground water, especially in urban contexts.⁴

Unfortunately, the EICV does not give any information about the construction of the pits used in latrines or on whether these provide sufficient containment of the liquid waste from ground water. We do, however, know that the percentage of households with access to improved sanitation, as

⁴ Rwanda State of Environment and Outlook, REMA/UNEP, 2009.

defined by the World Health Organisation/UNICEF Joint Monitoring Programme,⁵ has increased considerably over the past five years in Rwanda, from 59 to 75%, as shown in Table 4.3

Finally, the following three tables (Table 4.4, Table 4.5 and Table 4.6) give a picture of the construction materials used in houses in Rwanda (roofing, walls and flooring) and how this has changed over time. It is notable that considerable improvements can be observed; for example, the increase in households with cement floors, the growing trend of using bricks for walls rather than tree trunks, or the switching from thatched roofs to metal sheets (as encouraged by the government). All of these major trends are illustrated in Figure 4.4. The observed improvements in housing are a result of both economic development and settlement mobility – it remains to be hoped that these general developments are accompanied by similar improvements in environmental awareness and behaviour.

5 Energy resources

One major strain on the environment is the human use of fuels. For example, large-scale use of firewood can contribute to air pollution,⁶ especially through particulates, and this can in turn contribute to human health problems (especially when burning indoors). The excessive use of wood for fuel can also result in deforestation.⁷ A 2007 national forest inventory identified illegal logging and charcoal production as the main threats to the national forests of Rwanda.⁸

On the other hand, firewood is an essential day-to-day environmental resource that allows Rwandan households to maintain their standard of living. In addition, energy-related sectors such as charcoal production or the exploitation of methane gas from the bottom of Lake Kivu are bound to become increasingly important sources of employment and national income. The Vision 2020 and subsequent policy documents identify a reliable supply of energy as one of the key factors in ensuring continued economic growth.

Hence, a balance must be found between an energy supply that ensures economic development but makes sustainable use of natural resources in the long run. The Vision 2020 energy target is to connect substantial parts of the population to the electricity grid and to drastically reduce the use of wood in national energy consumption.

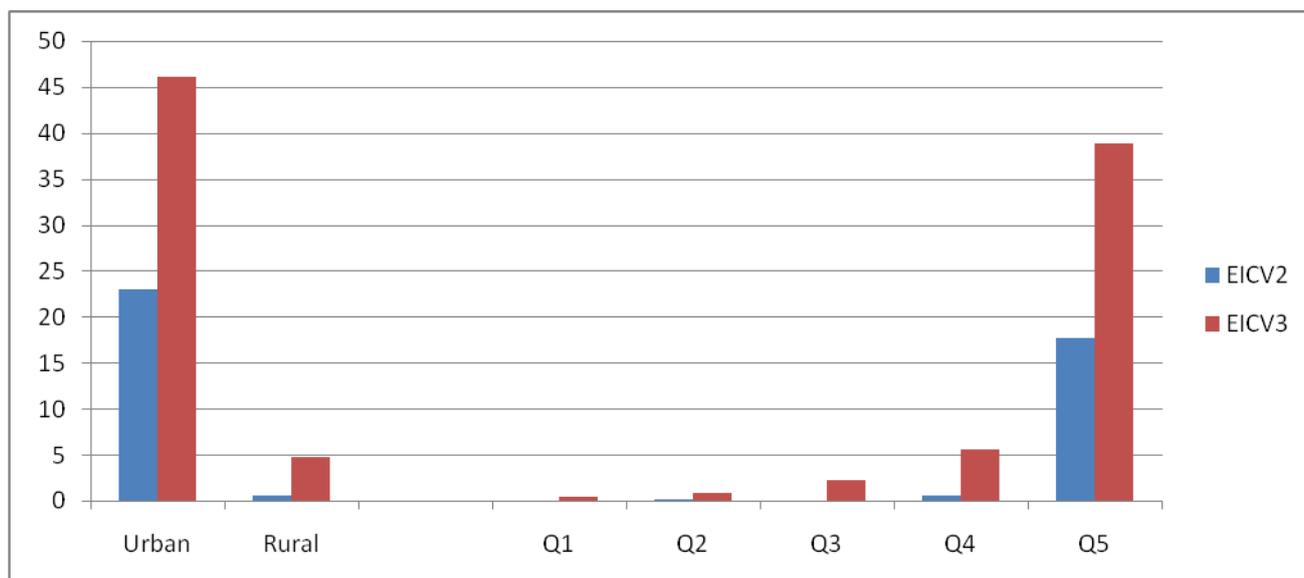

Table 5.1 and Table 5.2 below show the use of fuels for cooking and lighting in Rwandan households between 2005/06 and 2010/11. It is clear that firewood is still the fuel used for cooking by the vast majority of the rural population (93%). In the cities, charcoal is used by 51% of households, followed by firewood (45%). While rural households have not changed the fuels they use for cooking in the last five years, a slow trend can be observed in the cities away from firewood and toward charcoal.

⁶ In 2005, Rwanda still had one of the lowest emissions of CO₂ per capita in the world (see National Strategy for Climate Change and Low Carbon Development, Government of Rwanda, October 2011).

⁷ The environment sector EDPRS Joint Sector Review report 2010/11 estimates national forest cover to be at 22.1% in 2010/11. However, the same report warns that forestry statistics might be unreliable.

⁸ Cited in Rwanda State of Environment and Outlook, REMA/UNEP, 2009.

Figure 5.1 Changes in HH access to electricity (%)

Source: EICV3 and EICV2.

The percentage of households connected to electricity has increased substantially over the last five years, especially in the cities. As illustrated in Figure 5.1, the percentage of households with electricity there has doubled from 23 to 46%. Overall, 11% of households in Rwanda now use electricity as their main source of lighting, which is equivalent to approximately 243,000 households. Electricity access is particularly high in Kigali (56% of households). In the provinces outside Kigali, it is highest in the Western Province (8%) and lowest in the Southern Province (3%). Electricity use is heavily skewed towards the richest quintile (39% as compared to 6% in the fourth and 2% in the third quintile). However, even in rural areas the relative change between surveys is considerable. The figure also shows that the change over time has lifted the richest quintile to almost 40% in terms of electricity access. However, the third and fourth quintiles also saw relative increases in access.

The tables below also show that ‘green’ energy sources such as solar power or biogas play a negligible role in household energy use in Rwanda.

Source: EICV2.

In addition to fuel used in household cooking and lighting, private ownership of motorised vehicles is another source of demand for fuels. However, as illustrated in Figure 5.2 below, ownership of motorised vehicles in Rwanda is still very low. Despite some relative increases in car ownership in urban areas, it is still less than 5% of urban households that own a car and less than 2% that own a motorcycle.

Figure 5.2 Changes in private ownership of motorised vehicles (% of HHs)

So

Source: EICV3 and EICV2.

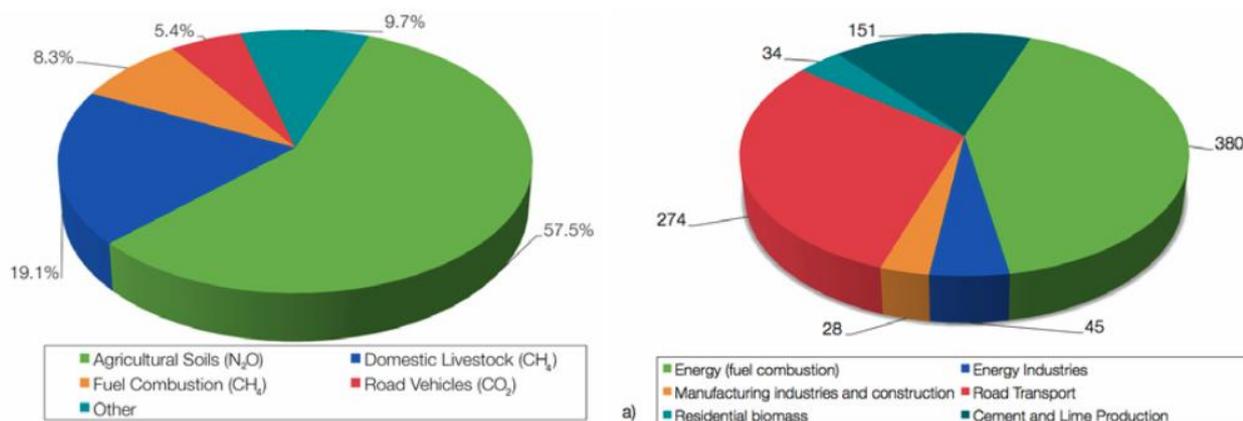

It is important to note that the ownership rates presented are for privately used vehicles only, i.e. they exclude vehicles for commercial use, including motos etc. A study commissioned by REMA in 2011 shows the number of vehicles registered in Kigali in 2009 and this shows that almost 35,000 motorcycles were registered in Kigali in 2009. Thus, commercially used vehicles should be considered an additional source of fuel demand as well as emissions.

In addition to household combustion of fuels and vehicle use discussed above, commercial/industrial use of fuels can also constitute a major source of energy demand. Given that the EICV survey is a household survey it cannot provide any information on such energy use. However, the 2011 National Strategy for Climate Change and Low Carbon Development provides an indicative overview of Rwanda’s emissions into the atmosphere in 2005, represented in Figure 5.3.⁹ Manufacturing industries and cement/lime production constitute one major source of CO₂ in Rwanda. However, the document also states that Rwanda has one of the lowest greenhouse gas (GHG) emissions per capita in the world. Nevertheless, emissions have shown an upward trend between 2003 and 2006 and are likely to rise further. Therefore, industrial demand for energy resources should also be considered in the context of environmentally and economically

⁹ The National Strategy document warns that ‘there are uncertainties in the GHG inventory due to inadequate representation, lack of basic data and application of emissions factors for different conditions. Owing to the rapid development in energy and industry in Rwanda, these figures need to be revisited to account for uncertainties in growth projections, energy intensity and the energy supply mix.’

sustainable supply of energy. Cleaner technologies in industries seem like an important way forward, and the REMA M&E report 2012 suggests that industries are beginning to adopt such technologies.

Figure 5.3 Rwanda’s key sources of GHG emissions and CO₂ inventory (in Gg) for 2005

6 Water resources

In addition to energy, another essential natural resource for human survival and development is water. Access to safe drinking water has a direct impact on people's quality of life, health, and productivity.¹⁰The EDPRS policy action for water resources is 'to ensure sustainable and integrated water resources management and development for multipurpose use (energy production, irrigation, navigability, safe drinking water...).'¹¹

Rwanda is divided into two major drainage basins: the Nile to the east and the Congo to the west. The country's hydrological network includes numerous lakes and rivers as well as its associated wetlands, which cover more than 10% of the country's surface.¹²

Water as a natural resource is required for domestic use, industrial use and agriculture. A 2005 Ministry of Lands, Environment, Forestry, Water and Natural Resources publication projected that domestic water use in Rwanda will more than double for most households between 2005 and 2020. Industrial and agricultural water use was also projected to increase drastically as the country develops economically.¹³This increasing demand will require careful management of the country's water resources.

The EICV does not collect data on the amount of water used by households. It does, however, allow insights into the types of drinking water sources that households use, and how they acquire their drinking water. Table 6.1 shows that access to improved drinking water sources as defined by the World Health Organisation/UNICEF Joint Monitoring Programme¹⁴has increased in Rwanda, from 70 to 74%. Kigali City has the largest percentage of households using an improved drinking water source (83%), with 35% of households using a public standpipe and 33% having water piped into their dwelling/yard. The proportion of households using surface water (rivers or lakes) as drinking water has decreased from 18 to 12%.

In addition to information on drinking water sources, we can learn from the EICV survey how far households in Rwanda need to walk in order to get to an improved drinking water source.¹⁵ Table 6.2 shows that rural households can now reach an improved water source more quickly than they could five years ago; 32% of rural households could reach an improved source in 0–14 minutes in EICV2, rising to 41% in EICV3.

Table 6.2 Time to improved water source

EICV3	Mean time to improved water source (minutes)	Time to improved water source (minutes)						No improved source	Total	Total no. of HHs (000s)

¹⁵ The EICV collects data on both geographical distance (in metres) and distance in terms of walking time. It is generally accepted that walking time is a more reliable measure and it appears more informative in the case of Rwanda, where terrain to the source might be steep or inaccessible.

Source: EICV2.

An interesting development can be observed when analysing household expenditure on water. In general, expenditure on water constitutes only a negligible proportion of household expenditure (less than 1%). However, there is a clear trend that fewer households receive their water for free when compared to five years earlier. In 2005/06, 81% of households paid nothing for their water whereas this was only true for 69% of households in 2010/11. The increase in households having water piped into their premises (as seen above) explains part of this development, but it might be helpful for the sector to further monitor this indicator in the future. As natural resources become scarce, there is always room for exploiting this scarcity. If water demand in Rwanda indeed grows as projected without an equivalent increase in supply, more households might see themselves facing water charges in the future.

7 Land management and agricultural practices

As stated in the sector’s EDPRS self-assessment, land is one of the three main factors of production and its finite nature makes it a very valuable natural resource. Use and management need to be carried out in a sustainable and rational manner.

Rwanda is a small country with total arable land of about 1.4 million ha.¹⁶ In addition, lands in Rwanda are used for pasture or exploited as arable marshlands. Figure 7.1 gives an overview of the development of land use between 1990 and 2002. This suggests that land is being farmed intensively and Rwanda cannot afford to let any land lie fallow.

Given a growing population combined with strong reliance on agriculture, it is clear that land is one of the scarcest resources in Rwanda. The EICV collects detailed data on land use and the agricultural activities of Rwandan households. Not being a specialised agricultural survey, it does not, however, provide information on the quality of soils.¹⁷

Figure 7.1 Changes in land use over time

¹⁶ Rwanda State of Environment and Outlook, REMA/UNEP, 2009.

¹⁷ For further information on agricultural production see EICV3 thematic report on agriculture.

7.1 Land distribution

The vast majority of Rwandan households cultivate some amount of land, and most of them are directly reliant on agriculture as their main or only source of income, especially in rural areas. Table 7.1 emphasises this as it shows that 98% of rural households cultivate land.

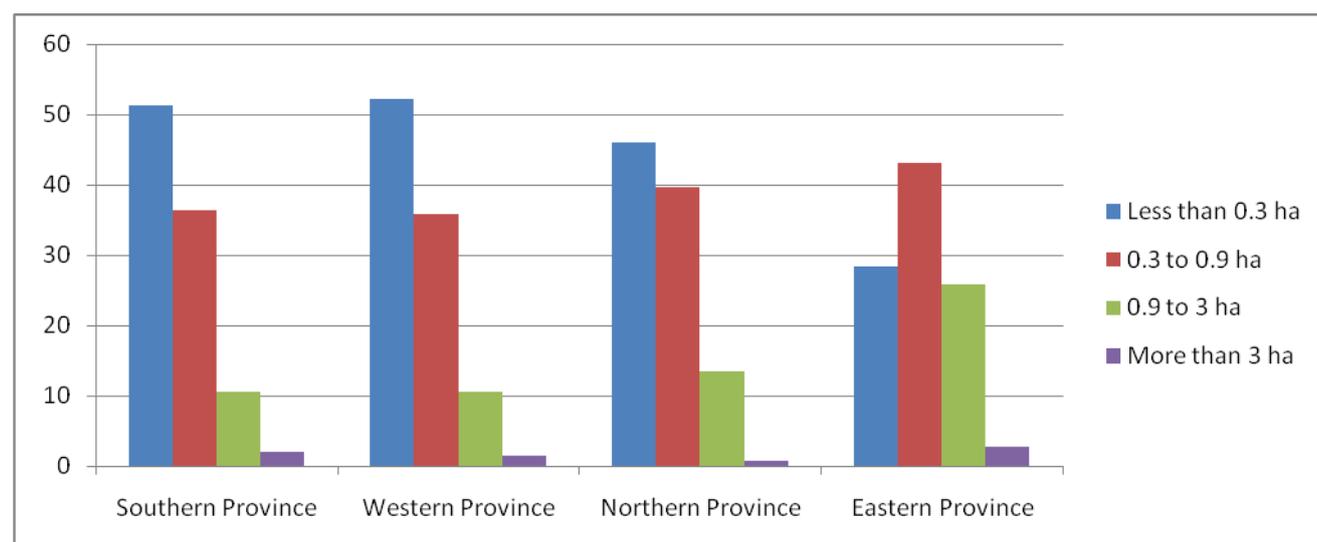

Table 7.1 % of HHs cultivating any land

	EICV3		EICV2

Source: EICV3 and EICV2.

The average area cultivated per rural household is only 0.6ha. FAO estimates that on average a Rwandan household requires at least 0.9ha to conduct sustainable agriculture.¹⁸ However, only 17% of rural households cultivate 0.9ha or more in Rwanda. This is also shown in Figure 7.2, which illustrates that the majority of households across all provinces cultivate less than 0.9ha, or even less than 0.3ha.

Figure 7.2 Distribution of total HH land in rural areas, EICV3

¹⁸ National Land Policy Report

With a growing population, land availability is becoming even scarcer over time. As illustrated in Figure 7.3, the average size of land cultivated per rural household has decreased in five years in all provinces except the Southern Province, where it was already lowest out of all provinces five years ago. This finding could have various different explanations but one possibility is that the Southern Province had already reached the point at which no further land sharing between parents and their descendants was possible. The important point to note here is that, in provinces other than the Southern Province, land cultivated per household has reduced between surveys, but it is now on average around 0.5ha across all provinces except Eastern Province – exactly the level at which no further reduction was observed in the Southern Province over the last five years. If the interpretation holds that below this level no further land sharing is possible, Rwanda might see a lot more young individuals without access to land in the Southern, Western and Northern provinces in the coming years. This possibility is further supported by the fact that the proportion of households cultivating less than 0.3ha has not changed much between the surveys, suggesting that there is a minimum amount of land under which no further sharing is possible if households wish to sustain themselves through agriculture.

It is of course clear that all data on land must be interpreted carefully in the light of the various government programmes of land consolidation, rehabilitation and registration that have been implemented over the past years.

7.2 Land ownership and usability as collateral

One of the strategic objectives of the land sub-sector is to ensure security of land tenure. Section 7.4 below provides detailed information on the LTR process, but before discussing the regularisation process itself it is helpful to understand first the overall dynamics of land ownership in Rwanda. This and the next section therefore present data on ownership and transactions of land in Rwanda.

Table 7.3 presents data on the different types of ownership or use arrangements that households have for their plots. It shows the proportion of households that cultivate land which was inherited, purchased, received as a gift, appropriated, sharecropped or leased. This shows that 70% of households own at least one parcel that was inherited. Furthermore, 45% of cultivating households own a parcel that was purchased (note that percentages for the different acquisition types do not sum up to 100% because households can own more than one plot, with different ways of acquiring them). As expected, quintile patterns differ for land ownership. Richer households are more likely to have purchased land whereas poorer households are more likely to have inherited land.

Comparison with 2005/06 shows a strong increase in the proportion of cultivating households owning a parcel that was purchased, and this is true across all the quintiles. It also shows an increase in households with land use arrangements involving lease or land received as a loan or for free.

Table 7.3 % of HHscultivating any parcel that was inherited, purchased, received as gift, received for free use or as loan, appropriated, sharecropped or leased

In addition to providing household income, land can be used as a security in times of hardship – either by selling it or by using it as collateral to request a loan. Table 7.4 shows that 84% of cultivating households have the right to sell their land or use it as a guarantee for a loan. There are

no strong differences in patterns across the different rural areas outside Kigali or across the different quintiles.

However, comparison with five years earlier clearly shows that the proportion of households that can sell their land or use it as a guarantee has increased substantially.¹⁹ This is likely to be caused by the LTR process discussed in more detail below in section 7.4.

The above table discussed whether households are in theory able to sell their land or use it as a guarantee. Table 7.5 below takes this discussion one step further as it investigates how many households actually used their land as collateral to secure a formal source of credit. It can be assumed that formal credits using land as collateral can only be obtained where secure land tenure exists. The data show that 10% of households in Rwanda were holding a formal source of credit in 2010/11. Out of those, 34% had used land as collateral to obtain the loan.

¹⁹ On gender relations, according to the Environment Joint Sector Review 2010/11, 84% of registered private land has women as owners or co-owners; unfortunately, this number is not comparable with the EICV figures given that the EICV does not record such data on land ownership.

Unfortunately, direct comparison with five years earlier is not possible because the EICV questionnaire changed in terms of categorising different sources of credit. Only data for EICV3 is therefore presented.

Table 7.5 % of HHs accessing formal sources of credit using land as collateral

7.3 Land transactions during past 12 months

The above data showed that the dynamics of land ownership changed quite considerably over the period 2005/06 to 2010/11. The tables above looked at land ownership types. A different way of looking at it is to analyse land transactions during the past 12 months. If land ownership dynamics have diversified we would also expect to see an increase in land transactions.

As seen in Table 7.6, this is indeed the case. The proportion of households selling and buying land increased, from 11 to 14% and from 6 to 9%, respectively. Likewise, there are more households than before which lent land to others or gave or received land as a gift, inheritance, dowry or otherwise. The average amounts spent and received in land transactions have also increased substantially; however, we cannot know whether this was due to larger plots being sold or the price of land increasing.

Table 7.6 Land transactions made during the last 12 months

7.4 Land tenure regularisation

The previous two sections shed light on the dynamics of land ownership in Rwanda as well as interactions on the land market. The increases in activity on the land market as well as the diversification of households' land ownership can be assumed to be in large parts due to the LTR process conducted by the government. According to the 2010/11 Joint Sector Review Report, 6,380,033 land titles had been issued by the time of that report. Table 7.7 summarises household exposure to the LTR process, as well as stages of the process. 54% of households had been exposed to the LTR in 2010/11, and most of those were at the stage of either having a claims receipt issued or having their land registered. Only 5% of households exposed to the LTR stated they had their land title issued already, and this was highest in Kigali.

Table 7.7 % of HHs exposed to LTR, and current stage of the process

7.5 Agricultural practices

One strategic objective of the land sector discussed above is the security of land tenure. Another strategic objective relates to the sustainable and rational use of land in Rwanda. Sustainable use of land is one that allows a family to derive good yields from their agricultural activity but does not degrade soil quality and thereby ensures the usability of lands for many generations to come.

Use of fertilisers is an important issue in this respect, because it allows a more efficient use of the scarce land resources but can also pose a threat of soil degradation if used incorrectly. The Government of Rwanda has decided to subsidise fertiliser use, and this can be seen in the data from the EICV. Table 7.8 shows that the percentage of cultivating households using chemical fertiliser has increased strongly from 11 to 29%. Use of organic fertiliser has also increased slightly, but it should be noted that the EICV collects information on expenditure on fertiliser, not usage. Hence, households that did not pay for their fertiliser (which may often be the case for organic fertiliser) will not appear in this statistic. Likewise, where the Crop Intensification Programme or other government programmes distributed any fertiliser free of charge, this will not count in the data presented below.

Table 7.8 % of HHs incurring expenditure on fertilisers (inorganic and organic)

Irrigation of lands is another important issue for the land sector, given that irrigation schemes allow increased cultivation of otherwise unused or underused lands. In a country where land resources are as scarce as Rwanda, this can help to mitigate the effects of decreasing land availability. The proportion of land irrigated is low, however, at only 3% overall. It is highest in the Eastern Province, at 4.4%.

The hilly geography of Rwanda has led to extensive soil degradation and soil erosion. About 40% of Rwanda's land is classified by the FAO as having a high risk of erosion and about 37% is estimated to require soil retention measures before cultivation. Only 23% of the country's lands is not prone to erosion.²⁰ Soil erosion control is therefore considered an important factor in ensuring Rwanda's economic development.

Table 7.9 also shows that the push towards erosion control has been successful. According to EICV3 respondents, 78% of land is protected against erosion. The EICV3's estimates (despite the EICV3 not being a specialised agricultural survey) are roughly in line with the estimates produced by the Ministry of Agriculture and Animal Resources. According to the Ministry's Annual Report 2010–2011, 87% of total land is protected from soil erosion.

The same table also shows the land area that was affected by land consolidation, with 12% being affected.

Table 7.9 % of land irrigated, protected against soil erosion, and affected by land consolidation

EICV3	% of land irrigated	% of land protected against soil erosion	% of land affected by land consolidation	Total cultivated land area (in 000 ha)
All Rwanda	3.0	78.1	11.5	1,228
Kigali City	4.2	74.4	2.0	72
Southern Province	3.1	84.9	6.1	292
Western Province	1.3	80.4	12.0	244
Northern Province	1.9	81.0	20.3	209
Eastern Province	4.3	71.0	12.1	411
Urban	3.3	73.3	8.8	101
Rural	3.0	78.5	11.7	1,128

Source: EICV3. Note: This table is based on all land parcels reported in EICV3. EICV3 is not a specialised agricultural survey and more reliable land area estimates should be obtained from the forthcoming agriculture survey carried out by NISR. However, it is important to note that the total land area estimate obtained from EICV3 (1.23 million ha) is relatively close to the official 2009 REMA estimate of 1.4 million ha of arable land in Rwanda.

8 Economic dimension of the environment and natural resources sector

The impact of the environmental sector on economic growth is very difficult to assess given that linkages are usually indirect rather than direct. It is safe to say that without the environment and natural resources, no economic development would be possible. The difficulty of measuring the impact of the environmental sector in official statistics is also mentioned with regret in the sector's self-assessment report, which in regard to the forestry sub-sector states that this 'has contributed much to the economic growth through different tree products even though that contribution is not well captured in the official statistics. It provides 90% of energy consumed in the country [and] is contributing to job creation through reforestation, harvesting, processing activities and commercialisation of forest products.' The same can be said of the other sub-sectors such as land or water. In neither of these cases is the link with economic growth directly measurable, despite the obvious fact that the majority of households make a living from their land or could not survive without access to water.

This chapter can therefore only provide some general information on the economic dimensions of the environment and natural resources sector and cannot provide a comprehensive answer to the question how it contributes to economic growth.

Table 8.1 presents data on the percentage of households working in and outside of agriculture. It shows that 72% of working individuals above the age of 16 have their main job in agriculture. This clearly shows that the natural resource of land is an important factor in the country's economy, and this is especially true in rural areas, where agriculture provides main jobs for 78% of the working population.

Table 8.1 % of population (16+) usually working in agricultural and non-agricultural employment

EICV3	Usual main job			Total	All 16+ years usually working (000s)
	Agriculture	Non-Agriculture	Other and n.i.		
All Rwanda	71.6	26.6	1.8	100.0	4,960

In addition to agriculture, there are further sectors relating to natural resources which provide jobs for the Rwandan population. Table 8.2 below shows the proportion of working individuals working in the forestry, mining, and recreation and tourism sectors. However, the estimates are very small and show that they currently do not constitute major sectors of job creation in Rwanda. Even so, the total number of jobs in mining has increased by some 60% over a five-year period.

The contribution of the mining sector to national GDP in 2010 was estimated at 1%,²¹ but it is one of the key export goods of Rwanda. The sector's 2010/11 Joint Sector Review Report estimates USD 116.8 million of total revenues from mineral exports.

Table 8.2 % of population (16+) usually working engaged in forestry, mining, and recreation and tourism sectors

As already mentioned in the quote above, another source of employment and economic development directly related to natural resources is the tourism sector, especially with regard to natural parks. Rwanda Development Board sources state that tourism revenue is increasing,²² and this also benefits local communities through revenue-sharing schemes injecting 5% of tourism revenues from park fees into local community projects.

²¹ NISR Statistical Yearbook 2011

²² NISR Statistical Yearbook 2011, but also discussed in Nielsen and Spenceley (2010): The success of tourism in Rwanda, Background paper for the African Success Stories Study, Joint Paper of the World Bank and SNV.

9 Human health and the environment

The objective of Vision 2020 is to have a satisfactory state of health for both the urban and rural population, which includes not being exposed to pollution. The EICV and RDHS both provide insights into health dynamics in Rwanda, and the general state of public health in Rwanda is discussed in detail in the latest RDHS report.

As with economic growth, the link between environment and health is difficult to capture through official statistics since the relation is not direct and often not measurable. Table 9.1 attempts a general overview of correlations between environment-related indicators and health complaints. However, it is important to note that this does in no way imply causality. People may be using unimproved drinking water sources and report health complaints, but this does not necessarily mean their water is making them ill – both indicators could simply be strongly correlated with another cause of illnesses such as malnutrition.

The table shows that health problems are higher among people that use non-improved sanitation, and also slightly higher among those using non-improved drinking water sources. Likewise, people lighting their homes with firewood have a higher incidence of health problems compared to others. Among cooking fuels, crop waste displays the highest correlation with health problems, but is similar for the more widely used firewood and charcoal.

Table 9.1 % of people reporting any illness over past two weeks, by environment-related characteristics

The RDHS 2010 report is the main document discussing public health in Rwanda, but the following four tables will give a general overview of four different diseases in Rwanda –diarrhoea, respiratory infections and malaria. All of these can be caused by unfavourable environmental conditions such as unhygienic water, air pollution, or infested swamps. Table 9.2 shows the percentage of children with diarrhoea, which was higher among children that had no access to improved drinking water sources or improved sanitation, and relatively high in the Southern Province. Diarrhoea prevalence is correlated with poverty; 16% of children in the poorest quintile were diagnosed with diarrhoea, as compared to only 11% in the richest.

Table 9.2 Prevalence of diarrhoea among children

	% of children with diarrhoea in last two weeks	% of children with diarrhoea with blood in last two weeks
All Rwanda	13.2	2.0
<6	6.6	0.7

10 Major problems related to the environment

The previous chapters discussed the interactions between humans and the environment, and how the Rwandan population benefits from its natural resources. However, sometimes the environment can also be a major source of destruction, such as through floods or destructive rains.

Table 10.1 shows that 44% of households in Rwanda have experienced some sort of environmental destruction. Most of these relate to reduction in harvests, either directly or through erosion, loss of soil fertility, destructive rains or droughts. As expected, rural households (which rely heavily on natural resources) are more susceptible to environmental destruction than urban households.

Table 10.1 Problems resulting from environmental destruction

EICV3	Problems resulting from environmental destruction										Total no. of HHs (000s)
