	100	100	100	100

NOTE: Source of data on targeted beneficiaries - Ministry of Labour and Welfare

prised 90.3 per cent of the total number of individuals receiving food stamps in 1994. These accounted for the largest share as intended. However, compared with the previous year, this represents a 2.3 percentage points reduction. The number of beneficiaries in both categories, however, continued to exceed targeted levels (up 2.6 and 9.5 percentage points in 1994).

The proportion of beneficiaries in the remaining categories fell below targeted levels. This was especially so with the case of Pregnant/Lactating Women. The recognition of the need to provide benefits to this group led to remedial steps to induce the expansion of this group. This resulted in a 1.9 percentage points growth relative to 1993.

Distribution By Area

The distribution of food stamps to categories by

area (See Table 5.3) shows that 69.3 per cent of food stamps went to individuals in Rural Areas, followed by the KMA, 16.2 per cent and Other Towns 14.6 per cent. However, there has been a growth in the distribution of food stamps to the KMA, while that for Other Towns remained fairly stable (See Table 5.4).

During the period 1990 to 1994, the percentage of individuals receiving food stamps in all regions grew by 3.1 percentage points, moving from 3.7 per cent to 6.8 per cent. Regionally, the proportion of individuals receiving stamps increased between 1990 and 1994 as follows: KMA from 1.2 per cent to 3.5 per cent; Other Towns 3.9 per cent to 5.4 per cent; and Rural Areas 4.9 per cent to 9.5 per cent. Growth was therefore strongest in Rural Areas, increasing by 4.6 percentage points. However, relative to 1993 the number of individuals in receipt of stamps in Rural Areas remained fairly stable

(a reduction of 0.9 per cent).

Distribution By Quintile

The distribution of benefits within quintile by category, shows that in the lowest and highest quintiles more than 80 per cent of the benefits went to Children Aged Less Than Six Years and the Elderly/Poor/Disabled categories. The distribution to each beneficiary category by quintile reveals that the proportion of benefits decreases with increasing consumption levels. This is reflected in a general reduction in the proportion of stamps allocated to the wealthiest quintile (1.7 percentage points), and an increase in benefits to the poorest quintile (5.5

percentage points) between 1990 and 1994 (See Tables 5.3 and 5.4).

COVERAGE OF HOUSEHOLDS

Regional Distribution

As in previous years more than half of the total number of households in receipt of food stamps were located in Rural Areas. The remainder were evenly distributed between the KMA and Other Towns (See Table 5.5).

In terms of the distribution of households in receipt of food stamps within each region, Rural Areas had

Note: a - within area b - across areas

the highest proportion, 28.2 per cent. This was followed by Other Towns with 15.4 per cent, and the KMA with 9.1 per cent (See Table 5.5)

The distribution of coverage enjoyed in the KMA, ranged from 9.4 per cent in 1990 to 16.5 per cent in 1994. In Rural Areas and Other Towns, the proportions decreased marginally, falling from 73.6 per cent to 68.1 per cent and from 17.0 per cent to 15.4 per cent over the period 1990-1994.

Between 1990 and 1992, the percentage of households receiving food stamps increased by approximately 2.7 percentage points. Within each region there was a marked increase in the percentage of households receiving food stamps (See Table 5.5). Since 1992 however, the proportion of households in Jamaica receiving food stamps has remained stable at approximately 20.0 per cent.

Distribution by Quintile

The proportion of total benefits which each quintile received showed the same pattern for households and individuals (See Table G-2 and G-5). The distribution of benefits across quintiles indicates a progressive decline in benefit as consumption rises, varying from 38.6 per cent for the poorest quintile to 5.6 per cent for the wealthiest. Over

the period 1990 to 1994 the share of benefits allocated to the poorest quintile increased by 5.0 percentage points while that for the wealthiest quintile decreased slightly (See Table 5.5). Compared with the previous year the allocation of benefits to the poorest quintile increased by 8.4 percentage points. Benefits to the wealthiest quintile however decreased by 2.0 percentage points.

Distribution by Category

For Jamaica as a whole, a disaggregation of the household data by categories shows that coverage for Pregnant/Lactating women was relatively low at 14.9 per cent. This however represents a significant improvement of 11.3 percentage points over 1993. Coverage in the Children under 6 years category was 28.5 per cent (See Table G-7), a decline of 3.0 percentage points relative to the previous year. Some 72.0 per cent of the elderly/poor/disabled in the sample were in receipt of food stamps, 31.9 percentage points above the previous year.

Number of recipients per household

As in previous years, households having one recipient made up the overwhelming majority of households receiving food stamps. The distribution of food stamps across recipient households remained

TABLE 5.6
DISTRIBUTION OF HOUSEHOLDS RECEIVING FOOD STAMPS
ACCORDING TO NUMBER OF RECIPIENTS IN HOUSEHOLD,
BY AREA AND QUINTILE, 1993-1994

	Number of Recipients in Household			
	Single Recipient		Multiple Recipient	
	1993	1994	1993	1994
Area				
KMA	86.0	70.0	14.0	30.0
Other Towns	72.2	77.0	27.8	23.0
Rural Areas	74.4	74.0	25.6	26.0
Jamaica	75.4	76.1	24.6	23.9
Quintile				
Poorest	62.9	71.0	37.1	29.0
2	76.5	71.0	23.5	29.0
3	78.7	78.0	21.4	22.0
4	83.9	91.0	16.1	9.0
5	96.8	95.0	3.2	5.0
Jamaica	75.4	76.1	24.6	23.9

virtually the same relative to 1993, with approximately 75 per cent going to single recipients and 24 per cent to multiple recipients.

Other Towns, with 77.0 per cent, had the highest proportion of households having one recipient, while the KMA had the largest proportion of multiple-recipients. This was unlike what obtained in the previous year. Relative to 1993 the proportion of multiple-recipient households in the KMA increased by 16 percentage points. In Other Towns there was a decrease in the proportion by 4.8 percentage points for the same period, while the proportion in Rural Areas remained unchanged (See Table 5.6). As was to be expected higher proportions of multiple-recipient households were from the lower consumption groups. In households having one recipient, the opposite was seen.

REASONS FOR NOT APPLYING FOR FOOD STAMPS

Of the 1,939 households in the sample, 80.5 per cent reported non-receipt of stamps. Of these, 67.8 per cent had never applied. The most frequent reasons households reported for not receiving food stamps continued to be perceived ineligibility, followed by the lack of knowledge of how to apply and the perception that it was 'not worth the trouble' (See Table G-8). The proportion of total house-

holds reporting all three major reasons remained fairly stable relative to 1993.

Across all areas, a large percentage of households did not consider themselves eligible for food stamps. This reason was also prevalent for households of the higher consumption groups.

Rural Areas had the largest percentage of households (24.7) who were unaware of how to apply for food stamps. In addition, although ignorance of how to apply was evident in all consumption groups, it was most prominent among households of the poorest quintiles.

It is noted that the proportion of households reporting reasons for not applying for stamps under the different categories remained fairly stable relative to 1993. However the large percentage of households that did not apply points to the need for improved dissemination of information about the programme. Similarly, applicants need to be informed of the results of their application. These initiatives should be conducted in view of achieving targeted levels. Ultimately, however, the recipients who have the potential to provide for themselves should be made increasingly self-reliant through the Special Rehabilitation Programme.

Housing

This chapter analyses 1994 data for the housing sector in terms of two major variables, location and income by quintile, as well as in terms of selected aspects of the housing stock since 1990. For the spatial analysis, the divisions used in earlier reports are maintained - the Kingston Metropolitan Area (KMA), Other Towns and Rural Areas. As in the past, the chapter closes with a look at expenditure patterns.

THE HOUSING STOCK

In 1994, some 78.6 per cent(1.) of the dwellings in Jamaica were detached units while 'Part of house' accounted for 13.7 per cent of the stock. Apartment buildings, townhouses, improvised units and dwellings made out of parts of commercial buildings, were numerically small, together accounting for only 3 per cent of dwellings. The KMA contained all improvised housing units and about 74 per cent of all apartments. The majority of commercial units used partly as dwellings was found in the Rural Areas.

When those dwelling types that contributed only small percentages of the total were omitted, there

was a statistically significant correlation(2.) between the degree of urbanisation and dwelling type. As the degree of urbanisation increased, the relative number of detached units decreased. In the KMA, 61.1 per cent of the units were detached rising to 82.2% in Other Towns and 90.3 per cent in the Rural Areas (See Table 6.1). Conversely, as the degree of urbanisation increased, so did the relative numbers of semi-detached units and parts of houses. About 67 per cent of the semi-detached units are found in the KMA compared to just over 21 per cent in the Rural Areas.

In all quintiles, detached units were the most numerous. However, while the differences among the four lower quintiles were insignificant the upper quintile stood out against the rest with 72.5 per cent of the households living in detached units compared to a mean of 83.3 per cent for the other quintiles.

In the case of 'Part of House', the variation among the three lowest quintiles was insignificant and, again, the upper quintile was different from the rest (See Table F.1). This type of dwelling was most frequent in the two upper quintiles, 13.2 per cent and 17.4 per cent respectively and, in terms of location,

TABLE 6.1
PERCENTAGE DISTRIBUTION OF SELECTED DWELLING TYPES BY LOCATION

TYPE OF DWELLING	KMA	OTHER TOWNS	RURAL AREAS
Separate House Detached	61.1	82.2	90.3
Semi-detached House	9.9	1.3	2.0
Part of a House	23.1	14.2	6.5

TABLE 6.2
PERCENTAGE DISTRIBUTION OF DWELLING TYPES, 1990-1994

DWELLING TYPE	SLC 90	SLC 91	SLC 92	SLC 93	SLC 94
Separate house, Detached	79.0	93.3a	83.5	77.3	78.6
Part of House	17.8	N/Aa	9.5	14.3	13.7
Semi-detached House	2.0	4.3	3.0	5.4	4.6
Apartment/Townhouse	0.4	1.1	3.1	2.2	2.4b
Part of Commercial Building	0.7	1.0	0.8	0.3	0.4
Other	0.2	0.3	0.2	0.4	0.2c

- a - The 'Part of House' category was excluded from the 1991 SLC questionnaire, hence the figure presented for 'Separate House, Detached' includes this.
- b - Presented separately in the SLC 94 data but combined for this Table.
- c - Includes 'Improvised housing unit' which is not found in earlier surveys.

were located predominantly in the KMA and Other Towns. To the extent that these units were created out of buildings originally intended for one household, they may have been one response to a scarcity of new construction. The consequence must have been some degree of overcrowding, at least at the level of number of households per building. While it may be presumed that, in the upper quintiles, buildings were large enough to accommodate two or more households comfortably, in the poorest quintile, with 11.4 per cent of the dwellings being parts of houses, there must have been some severe overcrowding.

If the 1991 figure for 'Part of House' is assumed to be about 13 per cent, it was only in 1992 that there was a significant change (See Table 6.2). The other years remain virtually the same. In 1992, the sample size was significantly different from the other years. More importantly, the sample design was also different.

A working hypothesis was that the relative numbers of apartments and townhouses should be increasing at the expense of detached units. The bulk of new

construction takes place in the urban areas where the price and scarcity of land for residential construction force adjustment by way of higher densities. This was not the case. Over the 5 years the contribution of apartments and townhouses was always minimal.

Two reasons are apparent. If apartment blocks and townhouses are becoming larger in size, they may be adding significant numbers of dwellings to the housing stock without a commensurate effect on the composition by type of unit. Another consideration is that increases in the number of households in the urban informal sector, where detached units are the norm, would confound the theory. For example, in the KMA, the number of detached units increased by 9 percentage points between 1993 and 1994 while the relative number of apartment buildings had remained virtually the same and semi-detached units had decreased from 12.8 per cent to 9.9 per cent.

Construction Material

Stone, brick, wattle and daub and 'Other' types of

TABLE 6.3
PERCENTAGE DISTRIBUTION OF WOOD AND BLOCK AND STEEL BY QUINTILE

QUINTILE	WOOD	RANK	BLOCK AND STEEL	RANK
Poorest	47.6	1	27.3	5
2	37.8	2	40.4	4
3	30.0	3	48.7	3
4	27.0	4	52.1	2
5	15.8	5	63.3	1

material accounted for 3.9 per cent of dwellings (See Table E.2). There is no evidence that the contribution of these materials has changed significantly over the last two years, and, by extension, over the period covered by the surveys. Block and steel accounted for just 49.8 per cent of dwellings in 1994, a decrease of only 0.3 percentage point from 1993. The next most frequently used materials were wood, 27.5 per cent and concrete nog, 18.8 per cent.

There was a significant correlation between location and material used in outer walls. In the KMA, 16.4 per cent of dwellings used wood compared to 37.3 per cent in Other Towns and 31.8 per cent in the Rural Areas. In Other Towns and the Rural Areas, the percentages of dwellings with block and steel walls were both about 47 per cent but significantly lower than in the KMA with 54.1 per cent. Rural Areas did not have the highest percentage of wooden dwellings but were a significant 6 percentage points lower than Other Towns, 37.3 per cent.

The KMA had the highest percentage of nog dwellings, 23.0 per cent compared with 12.4 per cent and 18.2% in Other Towns and Rural Areas. On the other hand, among the quintiles there was little difference in the relative number of nog buildings. The mean was 18.8 per cent and the largest deviation was 1.9 percentage points.

There was a perfect negative rank correlation between the relative numbers of wooden buildings and buildings made of block and steel by quintile ($r_s = -1$). The data do support the common view that, as income increases, so does the consumption of block and steel at the expense of wood.

AMENITIES

Toilet facilities

The adequacy of sanitary services is an important indicator of the condition of the housing stock. Adequacy can be measured in terms of type of toilet and in terms of whether these facilities are being shared. A word of caution is, however, necessary in interpreting the figures for type of toilet. On ecological grounds, there are locations in Jamaica where pit latrines would be the suitable type of toilet. Further, there is nothing intrinsically inferior in pit latrines, provided they are properly constructed and maintained.

In 1994, 51 per cent of the households islandwide were reported as having flush toilets, with 26 per cent linked to sewers; 48.4 per cent had pit latrines and the rest had other arrangements. The figures for 'None', 0.1 per cent overall and 0 per cent in the KMA should be treated with care. They seemed low and may reflect attempts by some respondents to provide socially acceptable responses to the questions about toilets.

Based on this single indicator, and with the caveats noted above, living conditions in the KMA were significantly superior to conditions in Other Towns

TABLE 6.4

Other	0.4	0.2	0.6	0.7	0.6
None	0.5	1.5	0.5	0.1	0.1

a - Flush toilets were combined prior to 1994

with the Rural Areas lagging even further behind (See Table 6.4). In the KMA, 54.8 per cent of the households had flush toilets linked to sewers compared to the overall mean of 26 per cent.

Significantly fewer households in the Rural Areas shared their toilets, blunting somewhat the conclusion reached. In the Rural Areas, 81.8 per cent of the households had exclusive use of their toilet facilities compared to about 71 per cent each in the KMA and Other Towns (See Table F.3). In the 1993 report the point was made that sharing of toilets is a surrogate for overcrowding. If this is true, overcrowding is worse in Other Towns and the KMA than in the Rural Areas. Relatively fewer flush toilets than pit toilets were shared (See Table 6.5).

They are expensive to acquire and install and are usually located indoors. However, that over 50 per cent of pit toilets in the KMA and over 40% in the Other Towns are shared should be a cause for some concern about the maintenance of these facilities and, therefore, about their effect on health.

As with other variables, there were no significant changes in the relative access to pit latrines and flush toilets over the past five years except perhaps for 1991 (See Table 6.6). In 1994, as in other years, about half of the households in the island used pit latrines.

Because other types of toilet accounted for less than 2% in each quintile, the number of pit toilets can be taken as the complement of the number of flush toilets (See Table 6.7).

The data in this table are interesting. On the one hand, the distribution by quintile is expected.

There is a strong and significant inverse relationship between income and the relative number of pit toilets. Just over a quarter of the households in the upper quintile use pit toilets compared to 86.3% in the poorest quintile. On the other hand, that the relative number of households in the upper quintile who had to share was the highest of the quintiles was the opposite of what was expected. Again, however, this may have been related to the number of households in the higher quintiles who occupied parts of houses.

TABLE 6.7

3	59.4	23.9
4	45.1	28.8
5	26.6	40.9

Drinking Water

The source of drinking water is, perhaps, a more useful indicator of living conditions than type of toilet. If water has to be carried over long distances, hygiene can be affected as households try to conserve its use. Also, the fetching of water reduces the time available for other tasks. Furthermore, rain-water and water from wells, rivers and springs are not likely to be treated. In a country in which there have been typhoid outbreaks, these are important considerations.

The data in Table 8 show the sources of water by area for 1994. Wells and 'Other' have been omitted because their contribution was minimal. (See Table

TABLE 6.8
PERCENTAGE DISTRIBUTION OF DWELLINGS BY SOURCE OF WATER

AREA	PERCENTAGE OF HOUSEHOLDS WITH ACCESS TO				
	INDOOR TAP/PIPE	OUTSIDE PRIVATE TAP/PIPE	PUBLIC STANDPIPE	RIVER/LAKE/ SPRING/POND	RAINWATER (TANK)
KMA	66.3	26.8	5.1	0.0	0.1
Other Towns	42.5	28.1	18.5	1.0	8.7
Rural Areas	19.5	17.8	28.9	5.5	23.3

F.5). The hypothesis was that the Rural Areas would be the least well served and that more rural households would be using untreated water.

On the whole, the hypothesis was supported. The KMA was best served and the Rural Areas the worst. Over 28 per cent of the households in Rural Areas had to use untreated water from tanks, rivers and ponds. Nevertheless, a majority of the households in each location had access to potable water. The figures for the three areas were 98.2 per cent, 89.1 per cent and 66.2 per cent.

Almost 65 per cent of households in the upper quintile had access to indoor taps/pipes. This compared to a mere 7.0 per cent in the poorest quintile (See Table F.5). Conversely, more households in the poorest quintile than in any other quintile, 29.3 per cent, used outside private taps/pipes though the differences among the quintiles were less sharp than for indoor taps. The upper quintile was only 13.4 percentage points below the number in the poorest quintile.

The differences in the use of public standpipes were again large. In the upper quintile, a mere 8.6 per cent used this facility compared to 16 per cent in Quintile 4 and 35.6 per cent in the poorest quintile.

tile. What the data showed then was that, even in the poorest quintile, over 70 per cent of the households had access to treated water but that, in the lower quintiles, the issue was convenience. Significant fractions of the population in these quintiles had to use public standpipes.

Households in all quintiles used water from tanks. The lowest three quintiles had virtually the same percentage of households in this position but there was a sharp break between them and the upper quintiles (Table F.5). The percentage for the upper quintile was 8.3 per cent. This use of water tanks, therefore, may be partly a response by households, in all income groups, who do not have consistent access to publicly-supplied water.

To measure the level of deprivation in the poorest quintile and the Rural Areas, indices of dissimilarity were calculated³. For the Rural Areas, the reference distribution was the KMA's i.e., it was assumed that the distribution in the KMA was what should be aimed at. This index was 55.8 meaning that 55.8 per cent of households in Rural Areas would have to improve their source of water in some way before the distribution there would be the same as that in the KMA. Using the upper quintile as the reference, the index of dissimilarity

Rural Areas	183.8(277)	304.0(49)

NOTE: Values in brackets show the number of households analysed.

for the poorest quintile was 57.4.

In Table 9, it is shown that, with the exception of 1991, the small fluctuations about the mean over the years can be explained by way of the 'error' term. While the population has not enjoyed any improvement in the sources of drinking water over the last five years, it has not suffered any setbacks.

Using the relevant class marks, the weighted mean distances travelled to public standpipe and river/lake/pond, by area, were calculated (See Table 6.10 and Table F.6).

The pattern shown by the data support the general hypothesis that more time/distances have to be covered in the Rural Areas than in the KMA to fetch water. The weighted mean distance to a public standpipe in the Rural Areas was almost 6 times the distance in the KMA though almost the same as in the Other Towns.

Lighting

For the country as a whole, two sources accounted for over 95 per cent of the lighting used in households - electricity, 70.0 per cent and kerosene, 26.9 per cent. Nevertheless, there was a statistically significant association between location and type of fuel used for lighting. In the KMA, 82.9 per cent of the households used electricity and 11.1 per cent used kerosene. The comparable figures for the Rural Areas were 60.2 per cent and 38.0 per cent with the figures for Other Towns 70.5 per cent and 28.7 per cent.

The data indicated that at higher levels of income, more electricity is used than kerosene. In fact, the two distributions were not independent as the one was virtually the complement of the other (See Table 6.11). For each type of fuel, however, the differences among the quintiles were significant. In the upper quintile, 87.1 per cent of the households used electricity for lighting dropping steadily to 38.4 per cent of the poorest quintile. Conversely, 10.9 per cent of the upper quintile used kerosene compared to 59 per cent of the poorest quintile. This was the only quintile in which more persons used kerosene than electricity.

As indicated in the Table, the variation among the quintiles was greater for kerosene. The percentage of households in the upper quintile using electricity was 2.26 times that in the poorest quintile while the comparative ratio for kerosene was 5.41. Despite its cost, the use of electricity for lighting may be becoming insensitive to income. A major factor is the increased availability due to programmes as Rural electrification. If this is correct, over time the differences among the quintiles and the locations will diminish as electricity becomes the norm and its usefulness as an indicator of living conditions disappears.

For the first four years the variations in the number of households using electricity for lighting was insignificant (See Table 6.12). Even the change in 1994 over 1993 was small. However, it was significant that in each year the number of households using electricity was higher than in the preceding

TABLE 6.11

Other	0.3	2.6	0.4	0.2	0.7
None	2.3	N/A	1.9	2.6	2.4

year and that this was almost exactly paralleled by decreases in the number of households using kerosene. The reasons why the number of households using electricity has increased despite the cost of this fuel lies in its greater convenience relative to kerosene, rural electrification, the lower risk to users and that it provides better lighting. The increase will continue.

Kitchens

Ninety-four per cent of the households had kitchens. The data in Table F.8 show the distribution of households with kitchens and those with exclusive use of them. In each location, over 90 per cent of the households had kitchens and the differences among the locations were not significant. Access to kitchens is uniformly widespread in terms of location.

TENURE

There is considerable evidence that the perceived 'ideal' tenure in Jamaica is freehold. In 1994, just over 72 per cent of the households owned dwellings (Table F.9). These dwellings were occupied either by the owner's household ('Owned by Household Member') or by someone related to the owner ('Rent-free'). Rental had become important, with the figure for the island being 24.0 per cent.

As is evident in Table 6.13, there was a significant correlation between location and tenure. The percentage of owned units was highest in the Rural Areas, 83.8 per cent, and lowest in the KMA, 60.5 per cent, where the cost of acquiring a house made rental more frequent.

Two additional points are of interest. The first has

to do with the class 'Rent-free'. For this type of tenure, the differences among the locations were relatively small. The data do not allow any comment as to the type of household in this tenure. However, these households usually comprise family members or friends of the owners who have been asked to 'mind' the units while the owners are abroad or living elsewhere in the island.

The other point has to do with squatters. The distribution of squatters was logical: the KMA had the largest number but, overall, the number of squatters was small at 1.7 per cent of the total population there. One explanation could be that questions about house tenure were perceived as threatening by respondents in non-legal arrangements. Some of them might have provided what they regarded as socially acceptable answers. Another reason is that some respondents could have distinguished between tenure of the building and tenure of the land. Most land squatters own their unit so that, while some estimates put the number of land squatters at about 25 per cent of the population, the number of house squatters is minimal.

Relatively more households in the poorest quintile than in the upper quintile owned their dwellings. Based on the distribution in the poorest quintile, 23.6 per cent of persons in the upper quintile would have to improve their tenure status in some way before their tenure distribution became the same as that of the poorest quintile. (3.)

The highest frequency of ownership was in the poorest quintile, 83.8 per cent, and the lowest in the two upper quintiles, 73.7 per cent and 62.9 per cent respectively. This apparent paradox is explicable in terms of location. In rural locations, all households, including low-income ones, have

TABLE 6.13

Other	0.0	0.3	0.6	0.0	0.3

access to affordable land. In urban locations, more low-income households adjust to the scarcity and cost of land by constructing units on illegally occupied sites.

The relative number of rented units by quintile was consistent with and opposed to the distribution of all owned dwellings. This number was lowest in the quintile with most owned units and vice-versa. As a minor point, it was in the poorest quintile, with the largest number of owners, that the number of squatters was also the largest.

In both the KMA and Other Towns over 90 per cent of renters rented from private individuals or agencies (See Table F.10) with other types of landlord - relative, private employer or public agency, each accounting for less than 5 per cent of households in almost all other cases. In the Rural Areas, by contrast, although private individuals or agencies provided over 80 per cent of rented accommodation, this sector was not as strong here as in the urban areas.

Just under 10 per cent of households rented from relatives, a figure twice as large as that for the KMA and even larger for Other Towns. Private employers provided for 7.9 per cent of households.

Though there were statistically significant differences among the quintiles, no pattern was evident

and, in each quintile, over 80 per cent of the households rented from private individual agencies or individuals. The highest number of renters using private individuals or agencies was in the lowest quintile with a significant drop to quintile 2. The top three quintiles fell between these two and could be treated as group since the differences among them were small.

As with other temporal comparisons, the issue is whether there were significant changes. After 1990, there was no significant change in the relative number owned units. Similar comments can be made about the relative number of rented units: there has been only insignificant variation about the mean. The number of persons living rent-free increased between 1991 and 1992 but has remained steady since.

Water

Mean monthly payments for water in the KMA were \$267 falling through \$243 for Other Towns to \$247 for the Rural Areas (See Table F.12). For households with metered water supplies, the cost per unit of water consumed is constant across the island. Assuming that most households are metered, these data suggest no alarming differences in the consumption of water among the areas for households with access to publicly provided water. Also, payments for water as a percentage of total household consumption ranged slightly from a high of 2.4 per cent in the Rural Areas to 2.1 per cent for Other Towns and 1.8 per cent for the KMA. That Other Towns and Rural Areas consumed slightly less than the KMA but paid relatively more of their total consumption is a function of lower household incomes there.

The effect of income on the consumption of water was clearer when the quintiles were compared. Consumption in the poorest quintile was about 57 per cent that of the upper quintile. Of course, part of the reason for the higher consumption in the higher income households is that these households are more likely to have washing machines, cars, lawns and gardens and to use hot and cold water. Again, despite lower consumption, poorer households paid more of their total consumption on water.

Electricity

Electricity is more expensive than water. The grand mean payment for electricity was 2.4 times that for water and accounted for more than 5 per cent of total consumption islandwide (See Table F.13).

Since there was no significant difference among the locations in the percentage of total consumption spent on electricity, the differences in the amounts paid for electricity were proportional to differences in consumption. The average household in the KMA spent 1.6 times as much on electricity as the average household in the Rural Areas and 1.3 times

as much as a household in Other Towns.

The relative proportions of total consumption spent on electricity by the quintiles were not statistically different though the trend was for the higher quintiles to spend less. Again, therefore, consumption was a direct function of mean income with the poorest households consuming, on average, less than half the figure for households in the upper quintile.

Telephones

In examining living conditions in Jamaica, there are some problems in interpreting the data for telephones. A telephone is more of a good of choice than either electricity or water. This is reflected in the number of households analysed, 364 (19 per cent of the total) for telephones as against 1,237 (64 per cent of the total) for electricity and 930 (48 per cent of the total) for water. On the other hand, because it is more of a luxury its acquisition will be sensitive to household income and availability.

Outside the urban areas the mean monthly payments rose sharply from about \$525 to \$745. The data by quintile do not fit the theory: the mean figure for the poorest quintile was higher than those for Quintiles 2 and 3. But this is inconclusive. As indicated in Table shows, only 4 households were analysed in the poorest quintile and in Quintiles 2 and 3, there were 17 and 38 respectively. The following list shows the percentage of households with telephones over the last 5 years.

The high relative increase, over 200 per cent, is a function of the small base but the data indicate a clear trend. More and more households are acquiring telephones. They may be doing so because, despite the cost, telephones can contribute signifi-

Electricity	510	619
Telephone	462	364

household. They provide immediate contact with places anywhere in the world and their use can be strictly controlled. For these reasons, the cost-benefit of telephones is perceived to be very high.

In 1994, the mean payments for water and electricity had increased over 1993 (See Table 6.16). This was expected as the price per unit of water and electricity had also increased over the same period. In the case of telephones, however, the mean payment had decreased. This decrease cannot be explained in terms of the different composition of the sample in the two years. Both in terms of location and quintile, the differences between the two years were insignificant. It suggests then that the telephone is more of a luxury good than the other two and, hence, its use is more susceptible to control in the face of rising costs. Conversely, while some control of the use of water and electricity is possible, and has taken place, there is a level of consumption below which a household is not likely to fall.

RENTALS AND MORTGAGES

Rent

The mean monthly rent in the KMA, \$1,513, was significantly higher than the figure for the Other Towns and about twice as large as the figure in the

Rural Areas (See Table F.11). Whether the differences are a function merely of location or of a combination of location and quality of housing could not be discerned from the data. However, evidence from elsewhere suggests that some aspects of housing, for example, size of rented accommodation, are better in the Rural Areas. On other factors such as access to services, the urban areas and the KMA areas perform better and, therefore, the costs reflect this.

The differences among the quintiles was much sharper than among the locations. The mean monthly rent for the poorest quintile was \$193 dollars, a mere 11 per cent of the figure for the upper quintile. The rents for quintiles 2 and 3 were not significantly different but that for the next quintile was almost double. In the KMA, mean monthly rent consumed 11.3 per cent of total household consumption compared to 8.5 per cent in Other Towns and 9.1 per cent in Rural Areas.

Mortgages

The data for mortgage payments by location (Table F.15) were based on small numbers of respondents so caution should be used in extrapolating from the findings. The mean figure for the island, \$1,274, was 18 per cent less than 1993 and, contrary to what was predicted, given the inflation over 1993 and the increasing costs in the rental market. Another surprising finding was that the mean monthly mortgage payment was highest in Other Towns and not in the KMA.

Similarly, the numbers of households analysed by quintile were generally small with only two respondents, for example, in the poorest quintile. Still, for

TABLE 6.17
MEAN MONTHLY PAYMENTS FOR RENT AND MORTGAGES, 1990 - 1994 (\$)

ITEM	SLC 90	SLC 91	SLC 92	SLC 93	SLC 94

Rent(\$)	234	421	432	770	1136
% of Total Consumption	9.2	11.2	7.4	9.8	10.2
Mortgage/Rent	1.76	1.67	2.71	2.01	1.12

the population analysed, the correlation between rent and income was positive and strong. Because the numbers of respondents were low, no analysis by year is attempted.

As pointed out in the SLC 93 Report, by 1993, the annual rate of increase in mortgage payments decreased somewhat to 32 per cent from 70 per cent between 1990 and 1991. Between 1993 and 1994, the absolute figure decreased, contradicting a deeply held belief that mortgage rates had been increasing sharply over the last few years in response to inflation. The 1993 Report had argued that the introduction of the Graduated Payment Mortgage plan, 5 per cent mortgages and up to 90 per cent financing for mortgages explained the moderate increase between 1992 and 1993. These factors, however, cannot explain the decrease in 1994, especially when the majority of households analysed, 74 per cent of the total, came from the two upper quintiles.

The major reason could be that the number of respondents providing data on mortgage payments has been always too low to make inferences. In 1994, for example, that number was 120 and, in 1993, it was 72. Another could be that, in 1994, the relatively low mortgage payments for the quadraminiums in Greater Portmore could have brought the mean figure down.

Property Tax

Across the island, mean monthly property tax figures appeared surprisingly low at \$31 (See Table F.16). More interestingly, this figure was virtually the same as the mean for 1993, \$32.

In terms of location, the figure for the KMA, \$94, was dramatically higher than those for Other Towns and Rural Areas, \$18 and \$14 respectively. However, in no location were property tax payments more than 0.5 per cent of total consumption. Outside the upper quintiles, the differences among the quintiles were insignificant. In no quintile did mean property tax consume more than 0.5 per cent of total consumption. Based on the data,

property tax cannot be said to affect living conditions significantly.

Ownership of durable goods

Of the 16 durable goods about which questions were asked, 12.7 per cent of the island, perhaps representing the truly poor, owned none (See Table F.17). For the others, three classes of good were discernible. One class could be described as ubiquitous- goods found in at least 70 per cent of all households. Only one good, Radio/cassette player, fit this description and, therefore, is almost neutral as an indicator of living conditions. Another group consists of those goods found in between 40 per cent and 70 per cent of the households. These may be described as among the first goods acquired as a household's living conditions improve and are early indicators of improvements in living standards. If this description is correct, large fractions of the population have not yet reached the basic level indicated by ownership of these goods (See Table 6.18).

The third group of goods was found in between 10 per cent and 20 per cent of the households (See Table 6.19).

Sewing machines may have become scarce because of the increase in the purchase of ready-made

Washing Machine	97.2
Motor Bikes	99.0
Cars/Other Vehicles	91.9

clothes or in the greater use of dress-makers outside the home. Partly because of the island's terrain, bicycles are not as widely used as might be expected. Video and stereo equipment may be described as semi-luxury goods, acquired only after basics such as stoves and refrigerators.

The next group includes goods found in very few homes - apparently because they are luxury goods as in the case of air conditioners or, as in the case of phonographs, because they have been largely replaced (See Table 6.20).

With few exceptions, the KMA performed far better than Other Towns and Rural Areas in terms of the possession of the selected goods (See Table F.17). Data in Table 6.21 show the location quotients by quintile for selected goods found in at least 10 per cent of the households(4).

For almost every good analysed, the upper quintile was 'oversupplied' and the lowest two quintiles undersupplied with a dramatic undersupply in the poorest quintile.

A crude way of measuring the effect of income on

ownership of durable goods is by subtracting the figure for the poorest quintile for a particular good from the comparable figure for the upper quintile. Assuming that the percentage in the poorest quintile who owned a particular good was the percentage that would have owned the good 'in any case', the difference, d, between that figure and the figure for the upper quintile may be interpreted as being 'caused' by income. This interpretation, however, should not be taken to extremes as d excludes the effects of prior and intervening variables.

The differences for the semi-luxury goods, video and stereo equipment, were relatively small. This could have been because the general absolute poverty of all households constrained consumption of these goods. But the discrepancies in terms of the basics is troubling. In the context of the caution noted above, income in the upper quintile has enabled an almost 60 percentage points higher consumption of gas stoves, a 50 point higher consumption of refrigerators and a 37 point higher consumption of TV sets compared to the poorest quintile.

A PRELIMINARY INDEX OF HOUSING AMENITY

To attempt to summarise the findings from the survey, an Index of Housing Amenity was constructed using a simple additive scale. To construct this index, measures on each variable that were presumed to contribute positively to well-being i.e., that were measures of amenity, were used. The measures selected were detached units, block and steel walls, exclusive use of flush toilets, indoor taps, electricity, exclusive use of kitchens, ownership of

TABLE 6.21
LOCATION QUOTIENTS FOR SELECTED GOODS, BY QUINTILE

units and an index for durable goods. This index for durable goods was the mean of the percentage of all items in the list used, including 'None'.

The Index of Housing Amenity was the unweighted mean of the percentages of households enjoying these items and were calculated for location and quintile(5) (See Table 6.23).

Though the KMA had the best value, the differences among the locations were relatively small - a point already made in the discussion above. More importantly, all the indices are low. For the country as a whole, living conditions, as summarised by the selected indicators, are generally poor. The index for ownership of durable goods was significantly below the mean. They were 27.7, 23.1 and 18.1 for the KMA, Other Towns and Rural Areas respectively and, when omitted, the mean was improved. But, a significant part of the notion of 'good' living is concerned with consumption of durable goods.

The indices for the quintiles were as follows -

The indices confirm what has been discussed

QUINTILE	OVERALL INDEX OF HOUSING AMENITY	INDEX OF HOUSING AMENITY - EXCLUDING DURABLE GOODS
Poorest	39.8	45.2
2	48.7	53.2
3	54.7	59.5
4	58.7	63.7
5	63.4	68.3

above. Income is a 'better' predictor of living conditions than location, though there is overlap between the two variables. Relative to the upper quintile, the lowest two quintiles are doing poorly, particularly when the index for durable goods is included. Overall, less than 40 per cent of households in the poorest quintile are living at an appropriate standard as measured by the indicators chosen. If the consumption of durable goods is excluded, the percentage increases to just over 45 per cent. Again, however, the table also suggests widespread difficult living conditions. In the upper quintile, the 'best' quintile, depending on which index is chosen, between 32 per cent and 36 per cent of households were living in less than appropriate conditions. This was high.

Conclusion

LOCATION	OVERALL INDEX OF HOUSING AMENITY	INDEX OF HOUSING AMENITY - EXCLUDING DURABLE GOODS
KMA	59.9	64.5
Other towns	55.4	60.0
Rural Areas	51.8	56.6

Index for Durable Goods	27.7	23.1	18.1
TOTAL	479.4	443.0	414.4
INDEX OF HOUSING AMENITY	59.9	55.4	51.8

The comments at the end of the analysis in the 1993 Report are applicable to the 1994 figures. Over the period 1990 - 1994, there were few significant changes in the quality of the housing stock. Using flush toilets, indoor taps, use of electricity and ownership of unit, the indices of well-being for the period were - 55.7, 53.0, 53.7, 53.8 and 55.0 respectively, all virtually the same.

The major weakness with this index is that the number of items was low and the components used were components whose use may not reflect the income of a household. For example, a household in the poorest quintile could have access to indoor taps because the unit might have been 'passed down' as previous better-off occupants move out to better neighbourhoods. In addition, the use of electricity is becoming more and more widespread and ownership of units is, to some extent, negatively correlated with income.

An index based on consumption of durable goods presents some problems in a society where remittances from abroad in cash and as goods occur so frequently but unequally among the quintiles. However, such an index would be more sensitive than a measure based on physical criteria. Unfortunately, no information was available for the earlier years. What the data for 1994 did confirm, though, was that, based on the consumption of durable goods, conditions in 1994 were generally substandard. Large numbers of the population lived in poor conditions. These numbers are likely to increase in response to conditions in the environment.

In 1994, there were significant differences among the three locations in terms of most of the variables but income was more strongly correlated with these variables than location. This, too, was the case in the past.

TECHNICAL NOTES

Housing

1. It was decided not to calculate the error associated with each estimate of a proportion. However, assuming that $p=0.5$, the maximum error for proportions based on the total sample was 2.9 per cent ($\alpha=0.01$). Wherever the actual proportion was more or less than 0.5, the actual error was, of course, smaller.

2. In this section of the Report, all tests of correlation were done at the 99 per cent level of confidence.

3. An index of dissimilarity is based on the differences between the percentage distributions of two groups on a selected variable. Using one group's distribution as the reference, the index shows the percentage of individuals in the other group who would have to change their status so that their group's distribution would become the same as the reference group. The index is, therefore, a measure of relative deprivation. It can be calculated by dividing the sum of the absolute differences between the paired figures by 2 or by finding the sum of absolute values with the same sign. The index for source of drinking water, KMA versus Rural Areas, was calculated as follows. The KMA was the reference location.

The index below was the sum of differences with negative signs. The sum of the differences with positive signs is 56.1 and is different because the row percentages do not add to 100.

4. A location quotient is the ratio between an

actual distribution and a hypothesised 'expected' figure. It is found by dividing the actual distribution by the expected figure. A value less than unity indicates an 'undersupply' of a good and a value above unity an 'oversupply'. In the case of durable goods, the expected figure was the overall weighted mean for each good. The mean shows the percentage of households in each quintile that would have owned a particular good if the distribution of that good among the quintiles were random. For example, the island mean for gas stoves was 59.2 per cent (See Table F.17) and the actual figure for Quintile 1 was 24.7 per cent. Therefore, the location quotient for Quintile 1 was .417 [$24.7/59.2$], an undersupply. Put another way, given that, in the population as a whole 59.2 per cent of the households had gas stoves, Quintile 1 had about 41.7 per cent of the number of gas stoves it 'ought' to have had.

5. Any index of quality-of-life, such as this one is, is sensitive to the number and type and to their weightings. For example, all flush toilets could have been used instead of only flush toilets exclusively owned. Also, indoor taps could have been given 3 times the weight of ownership of kitchens.

There are no definitive indicators that should be included and, often, the choice of indicators is determined by what is available. The Index of Housing Amenity should, therefore, be interpreted only in terms of the indicators used and their weightings. It cannot be used to infer about living conditions generally. More rigorous techniques e.g., factor analysis, would be needed for more definitive analysis.

LOCATION	SOURCE OF WATER						
	Indoor	Outside private	Public standpipe	Well	River...	Rainwater	Other
KMA	66.3	26.8	5.1	0.0	0.0	0.1	1.6
