Preface

The Ministry of Social Affairs and Labour (MoSAL) and the Central Statistical Organization (CSO) of Yemen have the pleasure to present the results of the Labour Force Survey (LFS) for Yemen conducted in 2013/2014. The survey was carried out by the CSO with the technical and financial assistance of the International Labour Office (ILO) and SILATECH. The LFS generated representative data on employment, unemployment and other vital labour indicators both at the national level and at the level of the governorates of Yemen. The survey also provides information on income from employment and characteristics of former household members who are living abroad and persons participating in training programmes outside the regular educational system. The survey was administered quarterly to a nationally representative sample of 13,376 households drawn from 836 primary sampling units (PSUs) from the CSO's sample frame.

MoSAL and CSO would like to express their gratitude to the ILO whose technical and financial support was critical to the success of this survey. In particular, CSO would like to thank the following individuals: Mr. Mustafa Hakki Ozel (ILO-STATISTICS) for providing assistance at all stages of the survey, Ms Aysegul Tugce Beycan for preparing the statistical tables, and Mr. Farhad Mehran for designing the sample and preparing this analytical report.

The MoSAL would like to place on record its gratitude to the many members of CSO who participated in the successful implementation of the survey under the leadership of Mr. Khaled Al-Madany, who also organized the training of the interviewers and the coordination of the field operations. The survey faced many challenges including the implementation of the new international standards concerning statistics of work, employment and labour underutilization before their adoption by the 19th International Conference of Labour Statisticians (ICLS) (Geneva, October 2013). There were also important practical challenges due to the events Yemen underwent during survey implementation.

MoSAL and CSO hope that the data from the survey and the findings presented in this report will be useful to policymakers, international organizations, academics, and civil society organizations concerned with employment and labour market development, and will assist in formulating appropriate policies.

CSO Chairman
Dr. Hassan Thabit Farhan

Minister of Social Affairs and Labour
Dr. Amat Al-Razzaq Ali Hummad

Executive summary

The Labour Force Survey (LFS) 2013-14 is the second such survey that has been carried out in the last 15 years in Yemen. Similar to the first survey in 1999, the LFS 2013-14 was conducted by the Central Statistical Organization with assistance from the International Labour Office. More recently, CSO has conducted a population census in 2004 and a household child labour survey of adults and children in 2010. The primary objective of LFS 2013-14 was to provide current data on the employment and unemployment situation at national and governorate level using the preliminary version of the new standards concerning statistics of work, employment and labour underutilization adopted by the 19th International Conference of Labour Statisticians (Geneva, October 2013).

After reprocessing the LFS 2013-14 data according to the international standards of 1982 (13th ICLS) to make the results comparable to the definitions used in the population census of 2004 and the household child labour survey of adults and children conducted in 2010, the results show that the labour force participation rate has somewhat increased during the ten-year period from 2004 to 2013-14. Both the number of unemployed and the unemployment rate, measured on a comparable basis, show a slight increase from 2004 to 2010 before a sharp decrease in 2013-14.

The main results of the LFS 2013-14 are summarized in the selected indicators presented below. They show the labour market situation before the recent political and military events taking place in the country. The key findings are:

- In 2013-14, the working-age population (aged 15+) was 13.4 million, of which slightly more than one-half (50.8 per cent) were men.
- The labour force participation rate was 36.3 per cent. However the rate for men was considerably higher than that for women (65.8 per cent for men and 6.0 per cent for women).
- Less than one-third of the labour force had secondary or tertiary educational attainment. Qualification mismatch affected some 83% of the employed population in their main job, whereas 3.4% of the employed population in their main job with skills requirements below their educational attainment.
- Employment totaled 4.2 million, with women accounting for only 7.0 per cent. The vast majority of employment was in the informal sector (73.2 per cent). More than 81 the employed population had informal employment including about 8 per cent informal employment jobs in formal sector enterprises and other non-informal production units.
- About half of all employed persons were employees, and some 42.4 per cent were either own-account or contributing family workers.
- Employment was heavily concentrated in the services sector (55.6 per cent), particularly in trade (22.7 per cent) and public administration (12.7 per cent). Agriculture accounted for 29.2 per cent of total employment and industry for 14.5 percent.
- The overall unemployment rate was 13.5 per cent, considerably higher among women (26.1 per cent) than among men (12.3 per cent).
- The youth unemployment rate at 24.5 percent was almost twice the national average, though young people experienced relatively shorter spells of unemployment than adults.

- In total, more than 1.556 million persons were either time-related underemployed, unemployed or in the potential labour force as available non-jobseekers or unavailable jobseekers. The combined measure of labour underutilization was 27.1 per cent almost double the unemployment rate.
- There were 3.27 million persons engaged in own-use production, essentially women and mostly in subsistence foodstuff production. Among the own-use producers, a relative important group was also involved in labour market activities as unemployed (197,000) or as potential labour force (388,000).
- Average hours usually worked per week at the main job were about 44 hours, significantly lower among women (34 hours) than among men (45 hours). Some 6.8% of all employed persons reported to have more than one job or activity during the reference week.
- Average monthly earnings at main job were 52,500 Rials and somewhat lower for women (40,400 Rials) vis-à-vis men (53,300 Rials).
- The size distribution of earnings showed considerable inequality with about 23.8 percent of all employed persons earning less than two-third of the median monthly earnings (calculated at 35,000 Rials per month).
- In addition, the survey showed that some 87,500 persons participated in a training programme during the last 12 months. Most of them were men and the bulk of the training was provided by the government, 21.4% for military and defense and 30.5% for other types of training, in particular, literacy and numeracy, and health-related training programmes.
- Finally, there were 103,000 persons living abroad, mostly men and originally unemployed in rural areas.

The survey covered all civilian non-institutional households living in urban and rural areas of the country. During field operations certain sample areas could be covered due to particular circumstances. The basic elements of sample design and survey errors may be summarized as follows:

- The total sample size of the survey was 13,376 households, spread over the four quarters of the year. The non-response rate was 3.6%.
- The standard error of the estimate of the national unemployment rate was about 0.5 percentage point, equivalent to a margin of error of +/- 1.2 percentage point. The relative standard error of a typical estimate of 500,000 persons was 4.6% equivalent to a margin of error of +/- 45,000.
- The comparison of the survey estimates with data from administrative records on employees in public administration and on teachers in primary and secondary education showed a reasonable degree of agreement.

Selected labour force indicators
Yemen Labour Force Survey 2013-14

	Total	Men	Women	Youth (15-24 yrs)	Adults (25+ yrs)
Population (15+ yrs)	13,378,000	6,808,000	6,570,000	4,972,000	8,407,000

Participants in training programs	87,500	63,400	24,200	31,000	56,600
Migrants working abroad	103,400	102,000	1,000	23,700	75,000

Note: ¹ Details may not add-up to totals and in certain cases differ from data in Statistical Annex A due to rounding or missing values.

² Separate data on top occupations sorted for men and women, and for youth and adults are presented in the body of the text.

1. Introduction

The Yemen Labour Force Survey (LFS) 2013-14 was conducted by the Central Statistical Organization (CSO) with the support of ILO and Social Fund for Development (SFD) and in collaboration with the Ministry of Social Affairs and Labour and the Ministry of Planning and International Cooperation. The CSO has conducted population censuses and large-scale household surveys of different kinds in the past including: (<http://www.cso-yemen.org>)

Labour force survey	1999
Poverty survey	1999
Population and housing census	2004
Household income & expenditure survey	2005-06
Multiple Indicator Cluster Survey	2006
Demographic survey in four governorates	2009
Child labour survey	2009-10

Although these inquiries are based on different methodologies and varying concepts and definitions, they all provide data on the employment and unemployment situation of the population and may be explored for constructing estimates of the trends of the key indicators of the labour market in Yemen.

The Labour Force Survey 2013-14 (LFS 2013-14) offers a wealth of information on the current employment situation in Yemen. In particular, it provides data on the labour force, employment, unemployment and other components of labour underutilization, namely, time-related underemployment and potential labour force. The data have been processed in line with the new international standards concerning statistics of work, employment and labour underutilization adopted at the 19th International Conference of Labour Statisticians (Geneva, October 2013).² The main results including seasonal and regional variations are presented in the next section (Section 2)

In order to assess the evolution of the employment situation since 2004 when the latest population and housing census was conducted as well as 2010 when a household survey on adults and children was conducted, the LFS 2013-14 data have been reprocessed in line with the previous international standards (13th ICLS 1982).³ The main trends are also highlighted in section 2.

More detailed analyses of the data are presented in the subsequent sections of the report including data on the labour force participation of the working age population (Section 3) and the characteristics of the employed in terms of branch of economic activity and occupation (Section 4), status in employment, informal sector and informal employment (Section 5), hours of work and time-related underemployment (Section 6), employment-

² ILO, *Resolution concerning statistics of work, employment and labour underutilization*, 19th International Conference of Labour Statisticians, Geneva, 2013. <http://www.ilo.org/global/statistics-and-databases/meetings-and-events/international-conference-of-labour-statisticians/19/lang-en/index.htm>.

³ ILO, *Resolution concerning statistics of the economically active population, employment, unemployment and underemployment*, 13th International Conference of Labour Statisticians, Geneva, 1982. http://www.ilo.org/global/statistics-and-databases/meetings-and-events/international-conference-of-labour-statisticians/WCMS_221500/lang-en/index.htm.

related income (Section 7) followed unemployment including long-term unemployment (Section 8), potential labour force and persons outside the labour force (Section 9) and own-use producers including subsistence foodstuff producers (Section 10). The last two sections deal with the special questions or modules attached to the core labour force survey concerning participation in training programs (Section 10) and migrants working abroad (Section 12).

Annex A of the report presents a more complete set of statistical tables.⁴ The survey methodology including the survey design, the main concepts and definitions, sample design and field operations, as well as an assessment of the quality of the results are described separately in Annex B. A specimen of the survey questionnaire is reproduced in Annex C of the report. Finally, Annex D lists the names of all officials who participated in the conduct of the survey.

2. Main results

A national labour force survey measures the labour supply and the characteristics of the working age population of a country. The working age population constitutes the human capital of the nation and defines its potential labour supply. From an economic point of view, the national labour force is a factor of production and its aptitude and skill level contributes to the productivity of the national economy. From a social and political point of view, the national labour force and its components, in particular, the unemployed and the underemployed, form social groups of special concern. The main results of the LFS 2013-14 are shown in Table 1 below.

Table 1. Labour force summary indicators, Yemen LFS 2013-14			
(‘000)	2013-14	(%)	2013-14
Working age population (15+ yrs)	13'378	LFPR. Labour force participation rate	36.3%
• Labour force	4'850	Employment to population ratio	31.4%
- Employed	4'197	LU1. Unemployment rate	13.5%
(time-related underemployed)	9	LU2. Unemployment and time-related underemployment	13.6%
- Unemployed	653	LU3. Unemployment & potential labour force	26.9%
• Outside the labour force	8'528	LU4. Composite measure of labour underutilization	27.1%
(potential labour force)	894		
Own-use producers	3'270		

The working age population, 15 years old and over, living in regular households in Yemen constituted 13'378'000 persons in 2013-14. Among them, an estimated 4'850'000 persons were in the labour force, 4'197'000 employed and 653'000 unemployed. Among the employed, some 9'000 persons were time-related underemployed and among the persons outside the labour force, 894'000 persons were in the potential labour force. Finally, there were 3'270'000 own-use producers, 197'000 of whom in the labour force as unemployed seeking work for pay or profit.

The labour force participation rate, i.e., the percentage of the working age population in the labour force, was 36.3% indicating that only about one-third of the working age population was working or seeking work for pay or profit. The employment-to-

⁴ Data given in the Statistical Annex A may differ in certain cases from the data presented in the body of the report due to rounding errors and missing values.

population ratio, the percentage of the working age population who has employment, an indicator of the performance of the national economy in providing employment to its growing population, was only 31.4%.

The unemployment rate, defined as the percentage of the labour force that is unemployed, was 13.5%, indicating that roughly for every six or seven employed persons in the labour force there was one unemployed person. But the unemployment rate (LU1) is just one indicator of the unmet needs for employment in a country. Other indicators that take into account not only unemployment but also time-related underemployment and available potential jobseekers and other non-available jobseekers are shown in the right panel of the table. Accordingly, the combined rate of unemployment and time-related underemployment (LU2) was 13.6%, the combined rate of unemployment and potential labour force (LU3) was 26.9% and the overall composite measure of labour underutilization (LU4) was 27.1%.

- Trends over the last ten years

After reprocessing the LFS 2013-14 data according to the international standards of 1982 (13th ICLS) to make the results comparable to the definitions used in the population census of 2004 and the household child labour survey of adults and children conducted in 2010, the results show (Figure 1) that the size of the labour force and the rate of labour force participation have both somewhat increased during the ten-year period from 2004 to 2013-14.

Fig. 1 Trends of labour force summary indicators:
Population Census 2004, CLS 2010 and LFS 2013-14 (reprocessed according to 13th ICLS definitions)

The labour force participation rate (LFPR) increased from 39% in 2004 and 2010 to 42% in 2013-14. In parallel, the employment-to-population ratio (Emp-Pop) moved from 33% in 2004 and 32% in 2010 to 37% in 2013-14. These results are consistent with the general hypothesis of increasing labour force participation and employment in the course of development. At lower levels of development, subsistence agriculture is the dominant form of economic activity and the labour force participation in work for pay or profit is therefore low. Over time, economic activity shifts from home-based production to market oriented

activities in different sector of the economy. Thus over time labour force participation rate and employment is expected to increase both in absolute and relative terms, as industries and services expand in the economy.

According to the results of Figure 1, both the number of unemployed and the unemployment rate, measured according to the international standards of the 13th ICLS, show a slight increase from 2004 to 2010 before a sharp decrease in 2013-14. The total number of unemployed was 689'000 in 2004 and 901'000 in 2010, and decreased to 653'000 in 2013-14. In parallel, the unemployment rate was 16% in 2004 and 18% in 2010, and decreased to 12%.

- Quarterly trends

Although, the general decrease of unemployment over the years is confirmed by the quarterly trends within the year 2013-14, the quarterly movements of the labour force and employment show a reverse trend as shown in Figure 2.

Fig. 2 Quarterly trends of labour force summary indicators, LFS 2013-14

The labour force and the labour force participation rate as well as employment and the employment-to-population ratio show a steady decline over the four quarters of the year. The labour force participation rate stood at 38.6% in Q1, declined to 37.6% in Q2 followed by another decline to 35.7% in Q3, and further decline to 33.3% in Q4. The employment-to-population ratio moved downward in parallel with an almost five-percentage point difference. The quarterly change of the unemployment rate was somewhat different, It declined from 14.6% in Q1 to 13.6% in Q2 and 12.5% in Q3, before reversing upward to 13.1% in the last quarter Q4.

- Seasonal variations

The LFS 2013-14 was conducted over the twelve-month period from September 2013 to August 2014. The sample was designed to spread over the four quarters of the year

so that the survey results are representative of the employment and unemployment situation in each quarter (Q1 representing the summer quarter, 17 August to 1 September 2013, Q2 representing the fall quarter from 1 to 17 November 2013, Q3 representing the winter quarter from 1 to 16 February 2014, and Q4 representing the spring quarter from 1 to 16 May 2014).

Based on the quarterly results, approximate values of the seasonal variations of employment and unemployment can be computed by comparing the quarterly values of employment and unemployment with their corresponding annual averages. For example, the seasonal factor of employment in Q1 is 104 calculated as the ratio of the level of employment in Q1 (4'381'000) to the annual average level of employment in 2013-14 (4'197'000). The results are shown in Figure 3 below.

Fig. 3. Seasonal variation of employment and unemployment, LFS 2013-14

It can be observed that employment is highest in the summer (Q1), about four-percentage points higher than the annual average, and lowest in the spring (Q4), about five-percentage points below the annual average. Employment is essentially equal to the annual average in fall (Q2) and winter (Q3). The seasonal variation of unemployment is somewhat different. In the summer (Q1) and fall (Q2), unemployment is higher than the annual average, especially in the summer, and lower in winter (Q3) and spring (Q4).

As expected, the amplitude of the seasonal variation of unemployment is much greater than employment. The difference between the highest and lowest seasonal factors of unemployment is 23 (=115-92), while the corresponding value for employment is 9 (=104-95), indicating that everything else equal, unemployment varies much more than employment over the four quarters.

- Geographical disparities

The national results reported above mask great geographical variations in labour market activities in the country. The LFS 2013-14 data show that there was somewhat more labour force activity in the urban areas (38.0%) than in rural areas (35.8%). By contrast, the unemployment rate was somewhat higher in rural areas (13.8%) than in urban areas (12.4%).

The disparities among governorates are presented in Figure 4. The left panel shows the governorates ordered from highest to lowest labour force participation rates, while the right panel shows the governorates in reverse order from lowest to highest unemployment rates.

Fig. 4 Disparities among governorates LFS 2013-14

It should be borne in mind that given the relatively limited number of sample observations in each governorate, the survey estimates at governorate level have generally lower degree of precision than the national aggregates. Nevertheless, it may be possible to draw certain conclusions by grouping together governorates with similar rates of labour force participation and unemployment.

In particular, Figure 4 shows that there are three governorates with relatively high labour force participation rates and low unemployment rates:

- Dhamar
- Abyan
- Al-Hodeidah

At the other extreme, three governorates have relatively low labour force participation rates and high unemployment rates:

- Al-Daleh
- Mareb
- Shabwah

In the centre, there are three governorates that have mid-level labour force participation rates and mid-level unemployment rates:

- Ibb

- Laheg
- Amran

In between there are five governorates with relatively high labour force participation rates (i.e., above the national average, 36.5%), and also relatively high unemployment rates (i.e., above the national average, 13.5%)

- Sa'adah
- Hajjah
- Aden
- Al-maharah
- Sana'a

Vice versa, there are seven governorates with relatively low labour force participation rates and also relatively low unemployment rates:

- Al-baida
- Sana'a City
- Taiz
- Reymah
- Al-Jawf
- Al-mahweet
- Hadramout

In order to improve the understanding of the geographical pattern of employment and unemployment in the country, it would be instructive to review the social and economic characteristics of each governorate and examine the employment structure of each governorate by branch of economic activity (Table 15 in Statistical Annex A) and income from employment (Annex A-Table 31) as well as in terms of extent of informal sector and informal (Annex A-Table 18) and degree of labour underutilization (Annex A-Tables 24 and 44).

3. Working age population and labour force participation

- Working age population

Figure 5 shows the age pyramid of the population within the scope of the LFS 2013-14. The age-pyramid provides valuable information on the current structure of the population and to some extent on its past evaluation and future trend. It shows the distribution of the age categories of the population for men and women, separately. The Yemen age pyramid constructed based on the LFS 2013-14 has a typical symmetric form with a fairly large base and small top, reflecting a population of a relatively high birth rate, a relatively high death rate, and an average life expectancy.

Fig. 5 Age pyramid, LFS 2013-14

The young population (15-24 years old) constitutes about 21% of total population, significantly higher than the 16% world average. The dependency ratio measuring the number of dependents (children 0 to 14 years old and older population 65 years old and over) relative to the size of the core working age population (15-64 years old) is about 0.9 indicating that for every child or elderly there is on average just a little more than one person of core working age. The age pyramid at the lowest age groups reveals an almost equal number of children in age groups (10-14 years) and (5-9 years) and even lower number in the age category (0-4 years). This may reflect an undercount of young children in the survey or the beginning of the decline of the fertility rate in recent years.

The full working age population (15 years old and over) comprises the core working age population (15-64 years) and the elderly population (65+ years). According to the results of LFS 2013-14 as mentioned earlier, it is estimated that 13'378'000 persons were of working age, of whom 4'850'000 were in the labour force. This represents a very low labour force participation rate (36.3%) by world and region standards. The world's labour force participation rate according to ILO's estimates and projections of the economically active population was 64.3% in 2013, and 50.4% for Arab States.⁵

- Labour force participation

The labour force participation rate (LFPR) is an indicator of the level of labour market activity. It measures the extent of working age population who are economically active. It is defined as the ratio of the labour force to the working age population expressed in percentage terms. The breakdown of the labour force participation rate by sex and age group gives a profile of the labour force participation as shown in Figure 6.

⁵ ILO *Economically Active Population, Estimates and Projections (6th edition, October 2011)*, http://laborsta.ilo.org/applv8/data/EAPPEP/eapep_E.html.

Fig. 6 Labour force participation rate by sex and age group, LFS 2013-14

Like most other national LFPR curves, the curve of the male labour force participation rate of Yemen has an inverted-U shape. The male curve is above the female curve, reflecting a higher labour force participation of men at all age groups. The male curve increases at lower age groups reflecting the transition of young men leaving school and entering the labour market. It reaches a peak in the age group 35-39 years, before slowly decreasing as people leave and retire from the labour market at older ages.

The female curve is almost flat never reaching more than 10%. The peak labour force participation rate of women is 9.3% at age category (30-34 years). A second peak, 7.0%, is at the age category (45-49 years), perhaps indicating a return of married women into the labour market after the young children in the household attain school age.

Low female labour force participation is a common feature of most countries in the region, on average about 20.5% in 2013 in Arab States according to the ILO estimates and projections. The labour force participation of women in Yemen is however particularly low and requires further examination in terms of family responsibility and other factors retaining women from participation in the labour market. Analysis of data by marital status and presence of young children in the household may be helpful in this regard (Annex A- Table 51).

- Employment-to-population ratio

The juxtaposition of the LFPR curve and the corresponding curve showing the employment-to-population ratio brings out further information on the pattern of labour force activity of the working age population. The data are presented in graphical form in Figure 7 for men and women combined. The top curve is the labour force participation rate (LFPR) plotted by age group. Below it is the corresponding curve of the employment-to-population ratio (Emp-Pop). The shapes of the two curves (LFPR and Emp-Pop) are similar. Both increase at lower groups as young people leave the school system and enter the labour force and get employment. They reach a peak at the core working age of 30 to 34 years. They both then decrease as workers retire and leave the labour force.

Fig. 7 Labour force participation rate and employment-
population ratio
LFS 2013-14

The gap between the two curves represents unemployment. It can be observed that the gap is more pronounced in the lower age groups. In higher age groups, the two curves get closer to each other, reflecting the narrowing down of the unemployment rate in higher age groups.

The dotted line in Figure 7 is a horizontal line drawn at half height (about 25%) of the peak of the LFPR curve which is 50%, corresponding to the age category 30-34 years. The intersection of the dotted line and the LFPR curve at the lower tail of the distribution corresponds roughly to the median age of entry of young people in the labour force. It can be seen here to be about 21 years old. The intersection of the dotted line with the emp-pop curve is at a slightly higher age, at slightly more than 22 years of age. The analysis suggests that young people entering the labour force in Yemen should expect on average slightly more than one year of unemployment before getting their first employment. A parallel analysis at the upper tail of the distribution indicates that the median age of retirement is about 63-64 years, which by difference with entry age in the labour force (21 years) suggests that the expected length of working life in Yemen is about 42-43 years.

- Educational attainment

The skill level of the labour force is to some extent determined by the educational attainment of the labour force participants. In broad terms, it may be said that the larger the proportion of the labour force having secondary and tertiary (university) education, the higher the skill level of the labour force. Also, it is widely recognized that there is a close relationship between educational achievement and employment opportunities in most countries. In general, the higher an individual's educational attainment, the more likely the person would be participating in the labour force. Figure 8 presents the distribution of the labour force by educational attainment for men and women separately.

**Fig. 8 Educational attainment of the labour force
LFS 2013-14**

The data show that women in the labour force are relatively more educated than men. More than 33% of women in the labour force have reached secondary or tertiary levels of education, against about 31% among men. Slightly more than 13% of women in the labour force have university education against 7.4% among men.

The skill level of the labour force is not only determined by educational attainment, but also by on-the training. Therefore, a more complete analysis of the skill level of the labour force may be carried out by examining data on the work experience of the labour force and on the occupation characteristics of the employed population (Annex A– Table 14).

- Female labour force participation

The abnormally low figure of the labour force participation rate of Yemeni women requires more careful analysis. Three issues are examined below: the trend, the relationship with educational attainment, and the reported reason for not participating in the labour force.

The labour force participation rate of women as measured by the LFS 2013-14 was 6.0%. This figure is below the regional average for Arab States for 2013 (20.5%) and below the estimated value for Yemen in 2013 (25.9%) reported as part of the ILO estimates and projections of the economically active population. The main reason for these discrepancies is the differences in the concepts and definitions used in the different data sources.

The LFS 2013-14 measurement is based on the new international standards concerning statistics of work employment and the, employment and labour underutilization adopted by the 19th ICLS (Geneva, 2013), while the ILO regional average and Yemen estimates were based on the previous international standards concerning statistics of the economically active population, employment, unemployment and underemployment adopted by the 13th ICLS (Geneva, 1982).

The key difference between the two sets of international standards as mentioned is the distinction between work and statistical treatment of own-use producers and in particular subsistence foodstuff producers: According to the 13th ICLS, “persons engaged in the production of economic goods and services for own and household consumption should be considered as in self-employment if such production comprises an important contribution to the total consumption of the household” [paragraph 9(6)].

By contrast, according to the 19th ICLS, included in employment are only “persons who work in their own economic units to produce goods intended *mainly* for sale or barter, even if part of the output is consumed by the household or family “ [paragraph 30(d)]. Emphasis added. So persons who work in their own economic units to produce goods intended wholly or mainly for own or family consumption are not considered in employment.

The following tabulation converts the 19th ICLS definition to the 13th ICLS definition for comparison purposes:

	<u>LFS 2013-14</u>
Female labour force (19 th ICLS definition)	397,000
+ Female own-use producers of goods	+1,910,000
- <u>Unemployed female own-use producers of goods</u>	<u>-32,000</u>
Female labour force (13 th ICLS definition)	2,275,000

The adjusted result compared with the corresponding data from the population census 2004 and the child labour survey 2010 shows in fact an increasing trend of female labour force participation rate:

<u>Adjusted to 13th ICLS definition</u>	<u>Female labour force</u>	<u>Female LFPR</u>
Population census 2004	659,000	12.3%
Child Labour Survey 2010	776,000	12.2%
Labour Force Survey 2013-14	2,275,000	34.6%

The apparent increasing trend of female labour force participation rate based on the adjusted data is however at odds with the trend of female employment in paid jobs. Paid employment is typically measured with a higher degree of accuracy and is generally less dependent on the underlying definition than other components of employment.

	<u>Female employment in paid jobs</u>
Population census 2004	167,000
Child Labour Survey 2010	167,000
Labour Force Survey 2013-14	96,000

Given the inclusive nature of the trend of female labour force, it is instructive to examine the relationship of the labour force with educational attainment. Educational attainment is one of the strongest determinants of labour market outcomes in most countries. First, at higher levels of educational attainment, a woman's expectation of future earnings turns very high, increasing the opportunity cost of giving birth to, and raising children. Second, the longer a woman stays at school, the lower the chances of giving birth to many children. With smaller household size and less family responsibilities, the woman's time is freed to participate in labour force activities. The following data from LFS 2013-14

show the strong relationship between educational attainment and female labour force participation:

According to the LFS 2013-14, the labour force participation rate of women with primary education or lower was only 4.5%. It increased to 14.8% for women with secondary education and to a staggering 62.1% for women with tertiary education.

The LFS 2013-14 questionnaire includes a question addressed to persons outside the labour force on reasons they did not look for work or tried to start a business. Respondents could provide multiple reasons among the following answer categories:

1. Waiting to start a job which starts in the future
2. Do not believe there is a job
3. Tired to look for work
4. Do not know how to look for work
5. Waiting for recruitment by Civil Service Office or Private Office
6. There is no suitable job
7. Lack required skill or experience or qualification
8. Because studying
9. No need for work
10. Too old, or health conditions do not allow for looking for work
11. Full-time family responsibility
12. Resistance from family members
13. Other reason

Except for persons responding to answer category 1 who were currently available for work, all others are classified as outside the labour force. For ease of presentation, the answer categories 2 to 7 are grouped together under the heading “labour market reasons” and the other answer categories 8 to 13 are grouped as “personal or family reasons”. The percentage responses for women by level of educational attainment are given in the following diagram:

The results indicate that generally most women tend to give personal reasons for not participating in the labour force. But the percentage declines with educational attainment. Virtually all women with primary educational attainment (95%) are not participating in the labour force for personal reasons, mostly because of family responsibility followed by studying. The percentage declines to 89% among women with secondary education, and further declines to 79% among women with tertiary education.

In conclusion, given that the education attainment of women has increased in the last fifteen years in Yemen, one should expect that female participation in the labour force has also increased during that period.

Branch of economic activity and occupation

- Employment in broad branches of economic activity

Branch of economic activity refers to the activity of the establishment in which an employed person worked during the reference period. An establishment may be a farm, a mine, a factory, a workshop, a store, an office or a similar type of economic unit. It is important to distinguish enterprises from establishments. "Enterprise" is a broader concept than "establishment". An enterprise is a legal entity (or group of legal entities) and may have a number of establishments with different economic activities and different locations. Figure 9 shows the share of employment in main job in agriculture, industry and services.

Fig. 9 Share of agriculture, industry and services in employment, LFS 2013-14

The left panel shows the results excluding agriculture own-use producers who according to the 19th ICLS standards are not considered as employed. The data indicate that 29.2% of the employed persons had their main job in agriculture, 14.5% in industry and 55.6% in services. The branches of economic activities are grouped according to (ISIC Rev 4)⁶.

If agriculture own-use producers are added (right panel), the relative shares change to 40.9% in agriculture, 12.2% in industry and 46.9% in services. Agriculture own-use producers include persons who performed activities to produce or process for storage agricultural, fishing, hunting and gathering products for own final use, as well as those who performed activities for own final use to collect or process for storage mining and forestry products, including firewood and other fuels, or to fetch water from natural and other sources.

It is often argued that in the course of economic development there is migration of workers from rural to urban areas, from agriculture and other labour-intensive primary activities to industry and then to services. To verify this hypothesis, table 2 below shows the evolution of the distribution of employment in agriculture, industry and services over the last 15 years.

Table 2. Evolution of the distribution of employment (in main job)
in agriculture, industry and services
LFS 1999, Census 2004, and LFS 2013-14

	LFS 1999 ¹	Population census 2004 ¹	LFS 2013-14	
			Without agriculture own- use producers	With agriculture own-use producers
Total	100.0%	100.0%	100.0%	100.0%
Agriculture	43.9%	31.0%	29.2%	40.9%
Industry	5.6%	6.9%	14.5%	12.2%
Services	42.5%	52.7%	55.6%	46.9%

Source: ¹Central Statistical Organization, The General Population, Housing and Establishment Census 2004, The Third Report – Population Economic Characteristics, Part One Sections One to Ten, p. 132. http://www.cso-yemen.org/publication/census/third_report_economic_part1.pdf

The data in Table 2 shows that the share of agriculture employment in main job has steadily declined from 43.9% in 1999 to 31.0% in 2004 and now to 29.2% in 2013-14. In parallel, the corresponding share of employment in industry has increased from 5.6% in 1999 to 6.9% in 2004 and 14.5% in 2013-14. Like in industry, the share of employment in main job in services has also increased from 42.5% in 1999 to 52.7% in 2004 and 55.6% in 2013-14.

More detailed analysis of the structure of employment by branch of economic activity and in relation to other variables such as sex, age-group, urban-rural areas, educational attainment, status in employment and occupation may be carried using the data in the statistical annex (Annex A – Tables 13, 14, and 15).

⁶United Nations, *International Standard Industrial Classification of All Economic Activities, ISIC Rev. 4* <http://unstats.un.org/unsd/cr/registry/isic-4.asp>. Agriculture refers to Section A of the classification; Industry to Sections B to F; and Services to Sections G to U.

- Top twelve occupations in main job

Occupation refers to the kind of work done by a person employed (or the kind of work done previously or wanted if the person is unemployed), irrespective of the branch of economic activity or the status in employment of the person. The International Classification of Occupations (ISCO-08) classifies occupations in 10 major occupational groups subdivided into 43 sub-major groups, 130 minor groups and 436 unit groups.⁷ The LFS 2013-14 provides data on the distribution of employed persons by major occupational groups in urban and rural areas, for men and women and broad age groups, separately (Annex A - Table 2). Skilled agricultural, forestry and fishery workers constitute the largest occupational group (1,178,400 persons), followed by service and sales workers (957,200). These two occupational groups cover more than half of the employed population.

The pattern is almost identical for young people (15-24 years old) and adults (25+ years old), although the distribution of occupations is slightly more concentrated among the youth than among adults. More than 33% of young people are employed in skilled agricultural, forestry and fishery occupations against 27% among adults. Similarly, more than 26% of young people are employed in service and sales occupations against 22% among adults.

The concentration of occupations may be examined in more detail at the unit level of the occupational classification. Figure 10 shows the top 12 occupations (4-digit occupations of ISCO-08) at main job among the total employed population, and among the youth separately. The top 12 occupations cover more than 60% of the total employed population, and more than 70% of the youth. In other words, more than 60% of employed people are engaged in the same 12 occupations. And, more than 70% of the employed youth is engaged in the same 12 occupations.

Looking at the top 12 occupations for the total employed population, one finds that field crop and vegetable growers (ISCO code 6011), shop salespersons and demonstrators (ISCO code 5220), dairy and livestock producers (ISCO code 6121) are top three occupation for both the youth and the employed population as a whole. At the fourth position, however, one finds waiters, waitresses and bartenders (ISCO code 5123) among the youth occupations and building construction labourers (ISCO code 9313) among the employed population as a whole. Similarly, one finds that primary and secondary education teachers among the top 12 occupations of the employed population, but not among the top 12 occupations of the youth. Instead, one finds farmhands and labourers (ISCO code 9211) and messengers, package and luggage porters (ISCO code 9151) among the top 12 occupations of the youth but not in the top 12 occupations of the employed population, in general.

⁷ ILO, International Standard Classification of Occupations, ISCO-08, <http://www.ilo.org/public/english/bureau/stat/download/res/futisco.pdf>.

Fig. 10 Top twelve occupations at main job, LFS 2013-14

Figure 10b shows the top twelve occupations of men and women according to the results of LFS 2013-14.

Fig. 10b Top twelve occupations at main job, LFS 2013-14

On the full list of occupations of men and women, the segregation of occupations among men and women may be measured with the occupational segregation index defined by

$$D = \frac{1}{2} \sum_i \left| \frac{n_{Ai}}{n_A} - \frac{n_{Bi}}{n_B} \right|$$

where n_{Ai} and n_{Bi} are, respectively, the number of men and women in a given occupational i and n_A and n_B are, respectively, the total number of men and women in all occupations. The occupational sex segregation index is one of the ILO decent work

indicators.⁸ It is a commonly used as proxy indicator for equality of opportunity in employment and occupation. It measures the extent of “male-dominated” and “female-dominated” occupations.

- Qualification mismatch in main job

Another topic that can be examined on the basis of the LFS 2013-14 results is the mismatch between occupation and education for the main job of the employed population. The qualification mismatch refers here to the situation where the educational attainment of the worker is above or below the skills requirement of his or her job. A simple approximate method that uses level of educational attainment and one-digit occupation data defines a mismatch when the educational attainment of the worker is higher or lower that the educational level required by the main current job. Figure 1 below shows the measurement of mismatch in terms of ISCO and ISCED, where the shaded areas represent mismatch.

Figure 1: Distribution of employed persons by occupation and educational attainment

ISCO - 08 Major Groups		ISCED-97 Educational attainment				
		0	1	2-4	5	6
		ISCO-08 Skill level				
		1st		2nd	3rd	4th
1	Managers	6,818	5,196	17,082	37,797	16,746
2	Professionals	7,072	15,128	42,128	233,288	1,605
3	Technicians, associate professions	21,884	38,327	45,505	61,576	13,510
4	Clerical support workers	32,552	117,937	135,524	25,438	119
5	Service and sales workers	430,271	689,838	203,376	56,342	234
6	Skilled agriculture, forestry, fishery workers	790,392	1,009,876	134,667	21,608	211
7	Craft and related trade workers	276,151	397,938	82,755	15,543	470
8	Plant and machine operators, assemblers	176,976	295,619	84,749	19,634	0
9	Elementary occupations	209,338	285,667	44,803	6,917	0

	Under- Qualification
	Over-Qualification

Figure 2: Mapping of ISCO-08 major groups to skills levels and ISCED-97 levels of education

ISCO-08 major groups	ISCO-08 Skill level	ISCED-97 Educational Attainment
1 Managers	3 + 4	5 - 6
2 Professionals	4	6
3 Technicians and Associate Professionals	3	5
4 Clerical Support Workers	2	2 - 4
5 Services and Sales Workers	2	2 - 4
6 Skilled Agricultural, Forestry and Fishery Workers	2	2 - 4
7 Craft and Related Trades Workers	2	2 - 4
8 Plant and Machine Operators, and Assemblers	2	2 - 4
9 Elementary Occupations	1	1

Source: ILO, *International Standard Classification of Occupations, ISCO-08*
<http://www.ilo.org/public/english/bureau/stat/isco/intro.htm>

⁸ ILO (2008), *Measuring Decent Work*, Discussion Paper for Tripartite Meeting of Experts on the Measurement of Decent Work, International Labour Office, Geneva, September 8th to 10th, 2008.

Figure 3: Skills mismatch in main job

ISCO		No Mismatch	Over-Qualified	Under-Qualified
1	Managers	65.21	0.00	34.79
2	Professionals	0.54	0.00	99.46
3	Technicians, associate professions	34.06	7.47	58.47
4	Clerical support workers	43.50	8.20	48.30
5	Service and sales workers	14.74	4.10	81.16
6	Skilled agriculture, forestry, fishery workers	6.88	1.12	92.00
7	Craft and related trade workers	10.71	2.07	87.22
8	Plant and machine operators, assemblers	14.69	3.40	81.91
9	Elementary occupations	52.25	9.46	38.29
	Total	17.10	3.35	79.55

The data indicate that about 205,000 employed working persons were working in their main jobs in occupations with skills requirements below their educational attainment, representing about 3.4% of the total employed population (i.e. over-qualification). The main category includes persons with university degrees working in occupations with lower skills requirements, mostly as technicians or associate professionals. On the other extreme, more than 4.8 million employed working persons were working in occupations with skills requirements above their educational attainment (i.e. under-qualification), representing about 80% of the total employed population. In conclusion, qualification mismatch affected some 83% of the employed population in their main job.

4. Status in employment, informal sector and informal employment

- Status in employment

Status in employment classifies jobs held by persons at a given point of time with respect to the type of explicit or implicit contract of employment of the person with other persons or organizations. It may refer to the current job or jobs of an employed person or the last job of an unemployed person who had with past work experience. The International Standard Classification of Status in Employment (ICSE-1993) identifies five main categories of persons with respect to their status in employment:⁹

- Employees: Persons working in “paid employment jobs”, i.e., holding explicit (written or oral) or implicit employment contract with remuneration not directly dependent upon the revenue of the unit for which they work. Remuneration could be in the form of wages or salaries, commission from sales, piece-rates, bonuses, or in-kind payments such as food, housing or training.
- Employers: Persons working on own-account or with one or a few partners in “self employment jobs”, i.e., (a) remuneration is directly dependent on the profits (or potential for profits) derived from the goods and services produced or for own consumption, and (b) engaging one or more “employees,” on a continuous basis.
- Own-account workers: Persons working on own-account or with one or a few partners in a “self employment job”, not engaging any “employees,” on a continuous basis.

⁹ ILO, *International Classification of Status in Employment, ICSE-93*, Fifteenth International Conference of Labour Statisticians, Geneva, <http://laborsta.ilo.org>

- Contributing family workers: Persons working in a market-oriented establishment operated by a household member, who cannot be regarded as partner, in a “self employment job”, not engaging any “employee” on a continuous basis.
- Members of producers’ cooperatives: Persons working in a cooperative producing goods and services, in a “self employment job”, not engaging any “employee” on a continuous basis

In the Yemen LFS 2013-14, the status in employment of the employed population was measured at their main job. The first category “employees” was divided into public and private sector employees and the last category “members of producers’ cooperatives” was not used. The results are presented in Figure 11 below. The data show that about half of the employed population is employees, 30.6% in the public sector and 19.6% in the private sector. The other half of the employed population is self-employed, 6.9% as employers, 31.0% as own-account workers and 11.4% as contributing family workers.

Fig. 11 Employed population by status in employment LFS 2013-14

Table 4 shows the evolution of the composition of status in employment over the last ten year. According to these data, the shares of employers and own-account workers appear to have steadily increased during the ten-year period. No clear trend for employees and contributing family workers may be observed from this table as it appears that contributing family workers have been combined with employees in part in 2004 and in full in 2010.

Table 4. Employed population by status in employment in main job
Population Census 2004, CLS 2010 and LFS 2013-14

	Population census 2004 ¹	CLS 2010 ¹	LFS 2013-14
Total	100.0%	100.0%	100.0%
Employees	60.6%	65.3%	50.2%
Employers	4.5%	4.6%	6.9%
Own-account workers	24.9%	30.2%	31.0%
Contributing family workers	10.0% ²	-	11.4%

Source: ¹ Central Statistical Organization, Statistical Yearbook, Table No. (5).

Note: ² Including worker apprentice/volunteer.

The combined proportion of own-account workers and contributing family workers in total employment is sometime considered as a measure of vulnerable employment.¹⁰ These two statuses of employment are thought to be particularly vulnerable when it comes to both economic risk and strength of the institutional arrangement. Such workers are said to be more likely to (a) lack contractual arrangements which can lead to a lack of job security and (b) lack the degree of social protection and social safety nets that govern wage and salaried workers and are therefore not likely to benefit from social security, health or unemployment coverage.

According to this measure, some 42.4% of the employed population had vulnerable employment in 2013-14. It would be instructive to compare the rate with comparable data from the LFS 1999, as well as the population census 2004 and the CLS 2010. In principle, many young people in both sexes work as contributing family workers, often combining schooling and work at the family farm or at the household enterprise. At later ages, the relative number of contributing family workers decreases and the relative number of employees increases as young people leave school and enter the formal labour market for the first time often taking an employee job.

- Employment in the informal sector

Many persons who cannot find a decent job with sufficient income try to earn a living by working as self-employed or employee in the informal sector. The concept of informal sector may be broadly characterized as consisting of units engaged in the production of goods or services with the primary objective of generating employment and incomes to the persons concerned. These units typically operate at a low level of organization, with little or no division between labour and capital as factors of production and on a small scale. Labour relations - where they exist - are based mostly on casual employment, kinship or personal and social relations rather than contractual arrangements with formal guarantees.¹¹

In the survey of Yemen LFS 2013-14, employment in the informal sector was defined as all persons 15 years of age and over who were engaged in small size units (less than 10 employed persons) excluding persons engaged in "establishments" in the sense of large enterprise or government unit or activities of private households as employers of domestic staff.

Based on this definition, there were 3'072'000 persons working in the informal sector in 2013-14, representing 73% of the employed population. The corresponding proportions for different categories of the population are shown in Figure 12. Accordingly, the incidence of employment in the informal sector was somewhat higher among men (73.4%) than among women (71.1%). The age pattern is U-shaped with relatively higher rates among young employed people 15-24 years old (83%) and the elderly 65+ years old (90%) than among the middle age groups. In terms of educational attainment, the data show

¹⁰ ILO, Guide to the new Millennium Development Goals Employment Indicators, Geneva 2009.
<http://www.undg.org/docs/10630/Guide-to-the-new-MDG-Employment-Indicators.pdf>

¹¹ Extract from ILO, *Resolution on the measurement of employment in the informal sector*, adopted by the Fifteenth International Conference of Labour Statisticians (ICLS), Geneva, 1993.
http://www.ilo.org/global/statistics-and-databases/standards-and-guidelines/resolutions-adopted-by-international-conferences-of-labour-statisticians/WCMS_087484/lang--en/index.htm

a clear decreasing rate: 84% among employed people with primary education, 56% among those with secondary education, and 23% among those with tertiary education.

Fig 12. Proportion of employed persons in the informal sector by sex, age group and educational attainment, LFS 2013-14

- Informal employment

The concept of informal employment refers to jobs as observation units as opposed to the concept of informal sector that refers to production units as observation units.¹² The two concepts are nevertheless related. Informal employment is a broader concept including (a) employment in the informal sector (except those rare employees in that sector who may have formal employment), and (b) informal employment outside the informal sector.

In the case of own-account workers and employers, the informal employment status of the job is determined by the informal sector nature of the enterprise in which they operate. Thus, own-account workers (without hired workers) operating an informal enterprise are classified as in informal employment. Similarly, employers (with hired workers) operating an informal enterprise are classified as in informal employment. All contributing family workers are classified as having informal employment, irrespective of whether they work in formal or informal sector enterprises.

For jobs held by employees, informal employment is defined in terms of the employment relationship. Four elements are identified. For a job held by an employee to be

¹² ILO, *Guidelines concerning a statistical definition of informal employment*, adopted by the Seventeenth ICLS, Geneva, 2003. . http://www.ilo.org/global/statistics-and-databases/standards-and-guidelines/guidelines-adopted-by-international-conferences-of-labour-statisticians/WCMS_087622/lang-en/index.htm.

considered as informal, the employment relationship should not, in law or in practice, be subject to national labour legislation, income taxation, social protection or entitlement to certain employment benefits (advance notice of dismissal, severance pay, paid annual or sick leave, etc.).

In the survey of Yemen LFS 2013-14, the operational definition of informal employment comprises all persons 15 years of age and over employed as a contributing family worker; employer or own-account worker of an informal sector unit; employee with no social security, or no paid sick leave, or no paid annual leave.

Based on this definition, there were 3'416'600 persons having informal employment in their main jobs in 2013-14, representing 81% of the employed population. The corresponding proportions for different categories of the population are shown in Figure 13. They follow similar patterns as employment in the informal sector except at a slightly higher percentage point in each category.

Fig 13. Proportion of employed persons with informal jobs by sex, age group and educational attainment, LFS 2013-14

Finally, Table 5 presents the joint distribution of informal sector and informal employment. It can be observed that virtually all persons in the informal sector have informal jobs. Only 2'200 employed persons in the informal sector have formal jobs. By contrast, a substantial number of persons engaged outside the informal sector have informal jobs (346'800). These are essentially persons with paid employment jobs engaged in formal sector enterprises on an informal basis, for example, as apprentice or temporary part-time employee, or as casual worker without contract, or sometime as home-based producer working outside the enterprise.

Table 5. Joint distribution of informal sector and informal employment, LFS 2013-14

Production units	Informal jobs	Formal jobs
Informal sector enterprises	3'069'800 (A)	2'200 (B)
Other units of production	346'800 (C)	777'900 (D)

Employment in the informal sector:	$A + B = 3'072'000$
Informal employment:	$A + C = 3'416'600$
Informal employment outside the informal sector:	$C = 346'800$

5. Hours of work and time-related underemployment

- Hours of work

The international definition of employment is expansive covering even one hour during a week. It is thus important that employment is analyzed in conjunction with data on hours of work in order to distinguish the various intensities of employment. Data on hours of work are also necessary to calculate time-related underemployment as well as average wages per hour so that the resulting wage data are comparable across different categories of workers.

The international standards on the measurement of working time recognizes several concepts of hours of work serving different purposes including contractual hours of work, normal hours of work, hours usually worked, hours actually worked, and hours paid for.¹³ Data on hours usually worked and hours actually worked at the main job are generally collected through labour force surveys. Many surveys also collect the data for all jobs, including subsidiary jobs as in the LFS 2013-14. Data on contractual hours, hours paid for are generally collected through establishment surveys and administrative registers. These sources also sometime provide data on normal hours of work and hours actually worked.

Hours actually worked are the time spent in a job for the performance of activities that contribute to the production of goods and services during a specified reference period. It includes the direct hours that the person is engaged in the activities, as well as the related hours such as waiting time, on-call, and resting time, coffee break, prayer, etc. It excludes annual leave, public holidays, sick leave and other leave, as well as commuting time between work and home, longer breaks such as meal breaks and educational activities, even if authorized by the employer. Hours usually worked are the hours actually worked in a job during a typical week (or in general any specific reference period). In principle, it may be

¹³ ILO, *Resolution concerning the measurement of working time*, 18th International Conference of Labour Statisticians, Geneva, 24 November – 5 December 2008. http://www.ilo.org/global/statistics-and-databases/standards-and-guidelines/resolutions-adopted-by-international-conferences-of-labour-statisticians/WCMS_112455/lang--en/index.htm

calculated as the most frequent number of hours that a person actually worked per week during the past month.

Table 6 gives the average hours actually worked and the average hours usually worked of the employed population at main job and at all jobs. The data show that employed persons worked on average slightly more than 35 hours during the reference week at their main job, and almost the same at all jobs. Their usual hours of work is significantly higher at slightly less than 44 hours per week at their main job and almost the same at all jobs.

Table 6. Average hours of work of employed persons
LFS 2013-14

	Hours actually worked during reference week	Hours usually worked per week
At main job	40.4 hrs	43.8 hrs
At all jobs	40.4 hrs	43.7 hrs

Corresponding data by demographic characteristics and by occupation and branch of economic activity are presented in the statistical annex A – Tables 20 and 21. The results show that the average hours usually worked in main job in the reference week is higher among men (44.6 hrs) than among women (33.7 hrs), and higher in urban areas (45.6 hrs) than in rural areas (42.0 hrs). Young people (15-24 years) worked on average slightly higher than adults (44.6 hrs versus 43.7 hrs). The highest average hours actually worked is in elementary occupations (43.9 hrs) and among domestic workers in activities of private households as employers (52.0 hrs)

- Excessive hours of work

The distribution of employed persons according to hours usually worked per week at all jobs provides information on persons working on short hours (time-related underemployed) and persons working long hours. Long or excessive hours of work as termed in the framework of decent work indicators is considered as a threat to physical and mental health, interfering with the balance between work and family life, reducing productivity and often signalling an inadequate hourly pay.¹⁴

Figure 14 shows that overall 29% of the employed population worked excessively long hours (more than 48 hours during the reference week) at all jobs in 2013-14. The incidence of long hours of work was higher among men (30%) than women (13%), and more in urban areas (37%) than in rural areas (industry (24%). In terms of occupations, the highest incidence is among service and sale workers (45%) and professionals (16%).

¹⁴ ILO, *Measuring Decent Work*, Discussion Paper for Tripartite Meeting of Experts on the Measurement of Decent Work, Geneva, September 8-10, 2008.

Fig 14. Proportion of employed persons with excessive hours of work (48+ hrs in reference week) at all jobs by sex, locality and occupation
LFS 2013-14

- Time-related underemployment

On the other tail of the distribution of hours of work, there are employed persons working short hours (less than 35 hours per week). Many of them are women and young people, in rural areas, working as contributing family workers in agriculture during the off-season. Short hours of work are a sign of labour underutilization. However, to the extent that short hours of work are voluntary or for non-economic reasons, it is not regarded as labour underutilization or time-related underemployment.

Time-related underemployment refers to persons in employment who, during a specified reference period of the survey: (a) wanted to work additional hours, (b) whose working time in all jobs was less than a specified hours threshold, and (c) who were available to work additional hours given an opportunity for more work. The data in Figure 15 show that there were very few employed persons in time-related underemployment in Yemen in 2013—14, less than 0.2%. The incidence was almost equal among men (0.20%) and among women (0.22%). Time-related underemployment was slightly higher in rural areas (0.3%) than in urban areas (0.1%), and highest among technicians and associate professionals (0.43%) followed by clerical support workers (0.35%).

Fig 15. Proportion of employed persons in time-related underemployment
by sex, locality and occupation
LFS 2013-14

6. Employment-related income

Employment-related income consists of the payments, in cash, in kind or in services, which are received by individuals, for themselves or in respect of their family members, as a result of their current or former involvement in paid or self-employment jobs. Income from employment excludes income derived from other sources such as property, social assistance, transfers, etc., not related to employment.¹⁵ Income from employment is generally divided into two parts:

- Income related to paid employment including direct wages and salaries in cash for time worked and work done, remuneration for time not worked, cash bonuses and gratuities, and remuneration in kind and services, profit-related pay and employment-related social security benefits.
- Income related to self-employment consisting of the profit or share of profit generated by the self-employment activity. It can be calculated as the difference between the value of gross output of the activity and the operating expenses. Income from self-employment includes remuneration received by owner-managers of corporations and quasi-corporation, where relevant. It also includes employment-related social security benefits received by self-employed persons.

¹⁵ ILO, *Resolution concerning the measurement of employment-related income*, adopted by the International Conference of Labour Statisticians, 16th ICLS, October 1998.

Data on income from employment were collected as part of the survey 2013-14. It covered the earnings of employees at the main job, in cash and in-kind, in principle, before deduction of taxes and any other deductions. The survey also collected data on monthly earnings of employers and own-account workers at their main job. For persons who could not or refused to provide data on earnings in Rials, the questionnaire offered the possibility of responding in terms of ranges of monthly earnings such as between 20,000 to less than 50,000 Rials or 50,000 to 100,000 Rials and so on. A similar procedure was adopted for obtaining data on earnings in secondary jobs or activities.¹⁶

- Average monthly earnings at main job

According to the results of the survey, the average monthly earnings of employed persons at their main job amounted to 52,500 Rials. Figure 16 shows the earnings differentials among men and women, and among different age groups and levels of educational attainment. On average, women received lower monthly earnings (40,400 Rials) than men (53,300 Rials). It is generally argued that women are more likely than men to work in the informal economy, and that the average earnings of women in the informal economy are lower than those of men in the informal economy.¹⁷ The results also show that the average monthly earnings of workers in the informal sector (46,100 Rials) is significantly lower than the average monthly earnings of workers in the formal sector (64,300 Rials).

Fig. 16 Average monthly earnings of employed persons by sex, age group and educational attainment, LFS 2013-14

¹⁶ The grouped data on monthly earnings were ungrouped at the processing stage using data on the distribution of monthly earnings obtained from those who provided earnings data in Rials. The procedure was applied only to data on main job as the earnings data on secondary job(s) were only collected as ranges.

¹⁷ Martha Chen, Joann Vanek, Francie Lund, James Heintz with Renana Jhabvala and Christine Bonner, *Progress of the World's Women 2005, Women, Work & Poverty*, UNIFEM, New York, 2005, pp. 46-50.

As expected, employed persons with primary educational attainment received on average lower monthly earnings (47,900 Rials) than workers with secondary educational attainment (53,100) and tertiary educational attainment (75,500 Rials). The data also show that the average monthly earnings of workers increase with age at core ages, as workers get more experience. The average monthly earnings of workers are about 34,500 Rials for young workers in the age category 15-24 years old, 46,200 Rials 279 in the age category 25-34 years old, and 62,200 Rials in the core age category 35-54 years old. After peaking at the age category 55-64 years old, the average earnings decrease with age as the skill of older workers gets less relevant with time.

It is generally recognized that the quality of earnings data varies depending on the status in employment. Income-related to self-employment is subject to relatively more response errors than the measurement of income-related to paid employment. Paid employees receive wages and salaries for their labour input. The payments received are generally known to the recipient. In contrast, self-employment workers earn income from work as part of the payment for the product or the services they provide and, therefore, the work-related income is not easily distinguishable from the other sources of revenues.

Table 7 provides data on the average monthly earnings of employment persons at main job by status in employment with distinctions between informal and formal jobs and between employment in informal sector enterprises and other production units. The results show that the average monthly earnings of employees at their main job (44,600 Rials) is below the overall average monthly earnings of employed persons in Yemen (52,500 Rials) and below the average monthly earnings of employers (109,700 Rials) and even own-account workers (51,500 Rials). Further analysis should clarify to what extent these differences were due to measurement errors or to differential degrees of economic risks of employers and own-account workers as compared to employees.

Table 7. Average monthly earnings at main job of employed persons by status in employment in informal and formal jobs and in informal sector enterprises and other units of production, LFS 2013-14

Rials	Status in employment at main job			
	Total	Employee	Employer	Own-account worker
Total	52,500	44,600	109,700	51,500
- Informal job	47,300	34,400	99,800	49,300
- Formal job	68,800	61,100	182,700	143,800
- Informal sector enterprise	46,100	26,000	99,800	49,300
- Other unit of production	64,300	58,900	182,700	143,800

The data also show that the average monthly earnings of employees are lower among those who have informal jobs (34,400 Rials) and still lower among those employed in informal sector enterprises (26,000 than Rials). Overall there is a gap of 20'000 Rials in monthly earnings of persons employed in informal sector enterprises against those employed in formal enterprises and other units of production. The gap is noticeably wider (about 80,000 Rials) between employers of informal enterprises and employers of formal

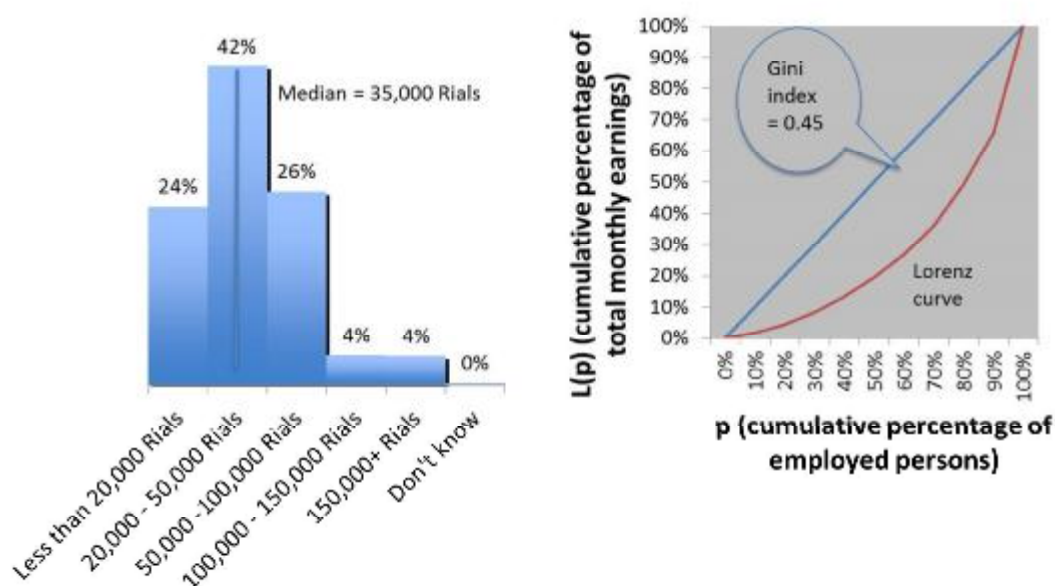

enterprises and other production units, and about the same amount (100,000 Rials) between own-account workers of informal enterprises and own-account workers of formal enterprises and other production units.

Finally, it is instructive to note that the average monthly earnings of employers and own account workers of informal sector enterprises are the same as the corresponding values for informal jobs. This is because for employers and own-account workers, the formal-informal status of their job is by definition the same as the informal or non-informal status of their enterprises.

- Earnings inequality

Figure 17 (left panel) presents the size distribution of monthly earnings of employed persons according to the results of the survey. The median of the distribution is 35,000 Rials per month, indicating that this point divides the distribution into equal parts with 50% of employees earning less than the median, and the other 50% earning more than the median. The median earnings is less than the average earnings (52,500 Rials per month) reported earlier, indicating a skewed distribution of earnings. As shown in Figure 17 (left panel), the distribution of earnings is concentrated on the lower tail of the distribution.

Fig. 17 Size distribution of monthly earnings of employed persons,
LFS 2013-14

The data on the size distribution of earnings may also be used to analyze the inequality of earnings among employed population. The right panel of Figure 17 shows the Lorenz curve of earnings distribution according to the results of the survey. The Lorenz curve is a graphical representation of the cumulative distribution of earnings, where the horizontal x-axis refers to the cumulative percentage of the number of employed persons and the vertical y-axis the cumulative percentage of total earnings. Thus any point in the Lorenz curve specified what percentage of aggregate earnings $y=L(p)$ is earned by the bottom x-percent of the employed population. Here it can be calculated that

The bottom 10% of the employed	earn about	2% of total earnings
The bottom 30% of the employed	earn about	8% of total earnings

The bottom 50% of the employed earn about 20% of total earnings

Similarly, one can calculate that

The top 10% of the employed	earn about	34% of total earnings
The top 30% of the employed	earn about	64% of total earnings
The top 50% of the employed	earn about	80% of total earnings

The diagonal line represents an equal distribution of earnings where every employed person receives the same amount of earnings. The area formed between the Lorenz curve and the diagonal line of perfect equality provides a measure of the degree of inequality of earnings of the distribution. The Gini index of inequality is equal to twice this area. The values of the Gini index range from 0 to 1. When the Lorenz curve is confounded with the diagonal line of perfect equality, the Gini index is 0, indicating perfect equality of earnings. On the other extreme, when the Lorenz curve lies on the horizontal axis except for one point, the Gini index takes on the value 1, indicating extreme inequality, i.e., when one person earns the total earning and the rest earn nothing. The Gini index of inequality of monthly earnings calculated on the basis of the results of the Yemen LFS 2013 is 0.45.

- Low earnings workers

Most people work to earn an income. Income from employment makes up a large proportion of household income and provides the basic resources of workers to maintain the welfare of themselves and the members of their family. In the latest version of the ILO framework of decent work indicators, low pay rate is defined as the percentage of the employed population whose average hourly earnings is below two-third of the median of the distribution or an absolute minimum, whichever is greater.¹⁸ Formulating the indicator in terms of a percentage of the median makes it independent of the national currencies and facilitates international comparison. The choice of two-third has the virtue of simplicity and wide applicability, including in countries that have either not adopted minimum wage legislation or which have set the statutory minimum wage far below the prevailing market wage.

Setting the threshold of low earnings at 2/3 of the median as suggested by the ILO Decent Work measurement, it can be calculated:

$$\begin{aligned}\text{Threshold of low earnings} &= (2/3) \times \text{median earnings} \\ &= (2/3) \times 35,000 \text{ Rials per month} \\ &= 23,350 \text{ Rials per month}\end{aligned}$$

Accordingly, employed persons earning 23,350 Rials per month in their main job in 2013-14 are considered as “low earnings workers”.

Figure 18 shows the percentage of low earnings by sex, age group and educational attainment. Altogether, some 24% of employed persons had low monthly earnings, i.e., earning less than 23,350 Rials per month in their main job. Low earnings affect men and women almost equally, 24% and 25%, respectively. Young people (15-24 years old) and the elderly (65 years old and above) had higher rate of low earnings (28%) than the middle-age

¹⁸ ILO, Tripartite Meeting of Experts on the Measurement of Decent Work, Geneva, 8-10 September 2008, Chairperson's report, paragraph 51.

workers. Workers in the core age group (35-54 years old) had the lowest rate of low earnings (20%).

Fig. 18 Percentage of low earnings workers by sex, age group and educational attainment, LFS 2013-14

As expected, the rate of low monthly earnings at main job decreases with educational attainment. Among workers with primary education, 28% had low monthly earnings. The rate among workers with secondary education was 16% and among those with tertiary education, it was only 9%.

The survey results also show that among informal main jobs was about 29% were low paid, while the rate among formal jobs was 2%. Similarly, about 30% of main jobs in informal sector enterprises were low paid, while the rate in formal enterprises and other non-informal production units was only 7%. The statistical tables presented in Annex A permit further analysis of low monthly earnings, in particular, to identify occupations, branches of economic activity and governorates with higher rates of low pay.

Finally it should be mentioned that the survey collected data on hours worked corresponding to the reported earnings of the employed persons. These data, not available in the present report, would permit the calculation of hourly earnings and low hourly earnings in line with the ILO recommendations on decent work indicators.

7. Unemployment

- Unemployment rate

The unemployment rate is the most commonly used indicator of the labour market. It is a measure of imbalance in the labour market representing the extent of unutilized labour supply of the country. It is also sometimes used in a general sense as an indicator of the health of the economy, not just the labour market. Unemployment rates for specific categories of the labour force, such as men, women, youth, adults, geographic regions, or specific occupations and branches of economic activity shed light on the groups of workers and sectors of the economy or regions most affected by unemployment.

As reported earlier, the LFS results indicate that there were 653'000 unemployed persons in Yemen in 2013-14, corresponding to a national unemployment rate of 13.5%. Figure 19 presents the unemployment rate by sex, age group and educational attainment. The rate of unemployment of women (26.1%) is more than twice the rate of men (12.3%). In terms of educational attainment, the results show that unemployment rate is highest among persons with secondary education (17%) and lowest among persons with primary education (12%). Persons with tertiary education have slightly higher rate of unemployment (15%) as the national average (13.5%).

Fig. 19 Unemployment rate by sex, age group and educational attainment, LFS 2013-14

In terms of age, young people (15-24 years old) have higher rate of unemployment (25%) than other age groups, almost twice the national average. There is a clear evidence of

an inverse relationship between unemployment rate and age. As persons get older, their risk of unemployment declines, but as shown later their duration of unemployment gets longer.

More than half of the unemployed (53%) had no past work experience. They were seeking employment for the first time. Among those with past work experience (47%), the majority were skilled agriculture workers (133'700), craft and related workers (117'800) and service and sales workers (101'400). In relation to the size of the labour force in different occupations, the unemployment rate was highest among craft and related trade workers (19.2%) and persons in elementary occupations (18.8%).

More detail analysis of the data in Annex A – Table 40 shows a decreasing rate of unemployment in occupations requiring higher levels of skill. This result combined with the fact mentioned earlier that unemployment rate among persons with secondary and higher educational attainment is higher than unemployment rate among persons with primary or lower educational attainment suggest that higher skill level decreases the chance of obtaining an initial employment, but when employed it reduces the risk of unemployment.

- Methods of search for employment

Figure 20 shows the methods used by the unemployed to seek employment in the four-week reference period of the survey. On average each unemployed used 2.2 methods (2.3 among men and 1.8 among women).

Fig. 20 Methods of search for employment LFS 2013-14

The most frequent method used by the unemployed to seek employment is assistance from friends and relatives (55%) followed by visiting potential employers (38%) and looking for work at market places (38%). Only 17% of the unemployed registered at the civil service bureau and just 13% applied at employment agencies.

The survey addresses a question to all employed persons on how the person found his or her current job (Q214). The results may be compared with those on methods used to seek employment. It should be borne in mind that the most frequent method to seek employment may not necessarily be also the most frequent method of finding employment.

- Duration of search for employment

Duration of unemployment is the length of time that an unemployed person has been without employment, available for employment, and actively seeking employment. In practice, what is measured in a survey is the duration of unemployment up to the time of the survey, i.e., the duration of search for employment. The duration of the complete spell of unemployment runs through the survey and beyond, and is not directly measurable by conventional labour force surveys.¹⁹

The international standards specify that “the duration of the search for employment, is measured from when unemployed persons began carrying out activities to seek employment, or from the end of their last job, whichever is shorter” (para 49). Here the duration is measured on the basis of the response to the survey question on how long have you been unemployed (Q404). There was more than fifty percent of non-response on this question. Figure 21 shows the distribution of the responses.

Fig. 21 Duration of search for employment
LFS 2013-14

Most unemployed have been seeking employment for less than six months (54%). Among those reporting duration, about 27% of the unemployed have reported to be seeking employment more than 12 months. According to the international standards long-term unemployment is defined as duration of search for employment lasting 12 months or more, including the reference period for the survey. Thus more than one-fourth of the unemployed were long-term unemployed in 2013-14.²⁰ The percentage was significantly higher among women (55%) than men (25%). Among young people 15-24 years old, long-term unemployment was about equal to the national average (26%).

Average duration of search for employment by unemployed persons (interrupted spells) was about 11 months. Based on calculations not shown here, the average duration of unemployment (completed spells) was estimated to have been about 39 months for the unemployed population as a whole and 50 months for the youth unemployed.

¹⁹ Kiefer, Nicholas, M & Lundberg, Shelly J & Neumann, George R, "How Long Is a Spell of Unemployment? Illusions and Biases in the Use of CPS Data," *Journal of Business & Economic Statistics*, American Statistical Association, vol. 3(2), April 1985, pp. 118-128.

²⁰ The analysis in the section on response errors in the methodological note suggests that there has been a tendency of over-reporting of duration of job-search in the LFS 2013-14.

8. Potential labour force and labour underutilization

- Persons outside the labour force

Persons of working age (15 years old and over) who were neither employed or unemployed during the reference period are classified as persons outside the labour force. It is instructive to note that there were more people outside the labour force (8'528'000) than inside the labour force (4'850'000) in Yemen 2013-14, mainly because of the low labour force participation of women. The reason for not participating in the labour force is shown in the left panel of Figure 22 below. The majority consists of persons who are outside the labour force because of full-time family responsibility (50.8%) followed by those are outside the labour force because of full-time school attendance (21.0%). The others are outside the labour force because of disability or inability to work (12.4%) or because of being retired or not wanting to work (3.0%).

The right panel of Figure 22 gives data on the educational attainment of the persons outside the labour force. It shows that the great majority (88.4%) had reached only primary education. In total about 11.6% had attained secondary or tertiary levels of education, considerably below the corresponding educational attainment of the labour force (30.8%). One factor explaining the difference between the educational attainment of persons outside the labour force and those in the labour force is the differential educational attainment of men and women in and out of the labour force (19.1% of men outside the labour force are with secondary or tertiary education against 27.6% in male labour force, while 8.6% of women outside the labour force are with secondary or tertiary education against 28.0% in female labour force).

Fig. 22 Persons outside the labour force
LFS 2013-14

- Potential labour force

Among the population outside the labour force, there are persons who have different degrees of labour force attachment. These people may potentially enter the labour force under favorable conditions. The international standards define the potential labour force as all persons above a specified age who, during the short reference period, were neither in employment nor in unemployment but who were considered as either (a) *unavailable jobseekers* (seeking employment but not currently available) or (b) *available potential jobseekers* (currently available for employment but did not carry out activities to seek employment).

Among the available potential jobseekers one may separately identify an important sub-category of discouraged jobseekers, comprising those who did not “seek employment” for labour market-related reasons, such as past failure to find a suitable job, lack of experience, qualifications or jobs matching the person’s skills, lack of jobs in the area, considered too young or too old by prospective employers).

The international standards further suggest the identification of a separate group with an expressed interest in employment not included within the potential labour force but relevant for social and gender analysis in specific contexts is the willing non-jobseekers, defined as persons “not in employment” who wanted employment but did not “seek employment” and were not “currently available”.

According to the results of LFS 2013-14, the potential labour force in Yemen comprised 894’100 persons, almost as many women as men. The bulk of the potential labour force was below 35 years of age (735’200) and in rural areas (749’500). Virtually all of them were *available potential jobseekers* (874’900), that is persons who were currently available for employment but who had taken any steps to seek employment during the past four weeks. The *unavailable jobseekers*, i.e., those who took steps to seek employment during the past four weeks but were not currently available for employment, were relatively few (19’200).

The significance of the concept of *potential labour force* is particularly valuable when it is compared with the conventional labour force in the case of women in Yemen. Figure 23 compares the size of the female labour force with the corresponding size of the potential labour force. It can be seen that the female potential labour force (450’100) was actually larger than the female labour force (396’600) in 2013-14. This is a remarkable result indicating the importance of the potential role of women in the labour force in Yemen.

Fig. 23 Female labour force and potential labour force, LFS 2013-14

The international standards introduce the additional concept of ***extended labour force***. It is defined as the sum of the labour force plus the potential labour force. Accordingly, the extended labour force of women in Yemen was 846'736. Expressed as a percentage of the size of the female working age population (15 years and over), the figure gives 13%, a rate more than twice as high as the measured labour force participation rate of women (6%).

- Composite measure of labour underutilization

Potential labour force together with time-related underemployment and unemployment are different dimensions of labour underutilization. Labour underutilization refers to mismatches between labour supply and demand, which translate into an unmet need for employment among the population. Other dimensions of underutilization of labour are skills mismatches and slack work, in particular, among the self-employed.

The international standards recommend the use of more than one measure of labour underutilization for monitoring labour market performance. The unemployment rate (termed as LU1 in the international standards) is the most restrictive measure of labour underutilization. The most expansive among those proposed by the international standards is the composite measure of labour underutilization (LU4), defined as the sum of time-related underemployment, unemployment, and potential labour force expressed as a percentage of the extended labour force.

The calculation of the composite measure of labour underutilization (LU4) on the basis of the results of LFS 2013-14 is presented in Table 8 below for the total working age population, and for men and women and the youth and adults separately. The results show that the composite measure of labour underutilization (LU4) is roughly twice the unemployment rate (LU1). The difference is particularly significant among women (65.5% combine rate of labour underutilization against 26.1% unemployment rate).

Table 8 Composite measure of labour underutilization
LFS 2013-14

	Total	Male	Female	Youth 15-24 yrs	Adult 25+ yrs
1 Labour force (2+4)	4,849,878	4,453,245	396,633	1,282,886	3,566,982
2 Employed	4,196,741	3,903,762	292,980	968,258	3,228,473
3 Time-related underemployed	8,584	7,948	636	<u>1,131</u>	<u>7,453</u>
4 Unemployed	653,136	549,483	103,653	314,629	338,507
5 Potential labour force	894,086	443,984	450,103	483,321	410,765
6 Labour underutilization (3+4+5)	1,555,806	1,001,414	554,391	797,950	749,272
7 Extended labour force (1+5)	5,743,964	4,897,229	846,735	1,766,209	3,977,754
8 Composite measure of labour underutilization (6/7)	27.1%	20.5%	65.5%	45.2%	18.8%
9 Unemployment rate (4/1)	13.5%	12.3%	26.1%	24.5%	9.5%

9. Own-use producers

- Own-use producers

According to the international definition, own-use producers are all persons of working age (15 years old and over) who were engaged in own-use production work for at least one hour during the reference period. Own-use production comprises any activity to produce goods or provide services for own final use, interpreted to mean production where the intended destination of the output as self-declared is mainly for final use by the producer in the form of capital formation, or final consumption by household members, or by family members living in other households. In the case of agricultural, fishing, hunting or gathering goods intended mainly for own consumption, a part or surplus may nevertheless be sold or bartered.

Production of “goods” in the sense of the 2008 SNA production boundary covers: (i) producing or processing for storage agricultural, fishing, hunting and gathering products; (ii) collecting or processing for storage mining and forestry products, including firewood and other fuels; (iii) fetching water from natural and other sources; (iv) manufacturing household goods (such as furniture, textiles, clothing, footwear, pottery or other durables, including boats and canoes); (v) building, or effecting major repairs to, one’s own dwelling, farm buildings, etc.

Provision of “services” goes beyond the 2008 SNA production boundary but is inside the General production boundary. It covers (i) household activities of accounting and management, purchasing or transporting goods; (ii) preparing or serving meals, household waste disposal and recycling; (iii) cleaning, decorating and maintaining one’s own dwelling or premises, durables and other goods, and gardening; (iv) childcare and instruction, transporting and caring for elderly, dependent or other household members and domestic animals or pets, etc.

Figure 24 shows the results of the measurement of own-use producers in the LFS 2013-14. The bulk of own-use producers, mostly women, were engaged in collecting wood or carrying water from other places mainly for own family consumption (2’116’000). Others were engaged in agriculture production or fishery mainly for own family consumption (344’000), raising birds, livestock, or sheep mainly for own family consumption (323’000), or involved in other production mainly for own family consumption, such as cleaning house, cooking (341’000). Almost two-third of the own-use producers were young people 15 to 24 years of age.

Fig. 24 Own-use producers
LFS 2013-14

Note: Almost two-third of own-use producers are in the age group (15-34 yrs old).

Almost half of the own-use producers were involved in both production of goods and provision of services (49%). The others were either exclusively engaged in the production of goods (26%) or exclusively in the provision of services (25%).

Among the own-use producers, some 2'423'000 may be classified as subsistence foodstuff producers. Subsistence foodstuff producers are a subgroup of persons in own-use production work. They are those who were engaged in own-use production of agriculture goods including fishing, hunting or gathering that contribute to the livelihood of the household or family.

- Own-use producers and the labour force

Own-use producers may be involved in labour force activity either working for pay or profit in their secondary activity or as unemployed jobseekers. According to the result of LFS 2013-14 shown in Figure 25, among the 4,27 million on-use producers some 197'000 were unemployed seeking work for pay or profit. The bulk of the unemployed own-use producers were men (76%) and virtually all in rural areas (95%).

Fig. 25 Own-use producers and the labour force
LFS 2013-14

Notes: ¹Including 2,423,000 subsistence foodstuff producers.

²The intersection of own-user producers and labour force also include in principle also own-use producers employed in a secondary activity for pay or profit, not measured in the survey.

The skip pattern of the survey questionnaire does not permit to identify own-use producers who were in paid or self-employment in their secondary activity. The survey however provides data on own-use producers who were outside the labour force as part of the potential labour force. In total there were 387'600 own-use producers outside the labour force who were either unavailable jobseekers or available potential jobseekers. They were mostly women (73%) and almost all in the rural areas (97%).

10. Participation in training programs

The formulation of employment policies requires rigorous analyses of the relationship between education and the labour market and in particular the role of training in insertion or reinsertion into the labour market. There is a two-way relationship between the education system and the labour market. The education system supplies the labour market with an educated labour force for the national economy, while the labour market – through the wage structure of occupations and other labour market variables – transmits signals on the types of qualifications expected from the education system.

Responding to the interest of Ministry of Social Affairs and Labour (MOSAL) on training policies and the relationship between training and labour market outcomes, the questionnaire of LFS 2013-14 was designed with a specific series of questions on training outside of the general education system. The resulting data are briefly analyzed to address the following general issues:

- The outreach of training among young people and adults in Yemen.
- The extent and nature of the demand for training in terms of subject of courses and type of training providers.
- The effectiveness of the training programmes for insertion of youth and adults into the labour market.

As shown in Figure 26, there were in total an estimated 87'500 persons who participated in at least one training course outside the regular education

Fig. 26 Participation in training programmes in past 12 months by sex, age group and educational attainment, LFS 2013-14

system during the past 12 months prior to the survey. The majority were men (72.4%), with secondary education (40%) and evenly distributed in the two prime-age categories, 15 to 24 years old (35.4%) and 25-34 years old (34.8%).

Among the multitude of subjects of training, three emerge by far as the most frequent. These are military and defense training (18.7%), learning languages (15.0%) and computing (14.8%). The bulk of the training was provided by the government, 21.4% for military and defense and 30.5% for other types of training, in particular, literacy and numeracy, and health –related training programmes. Other training providers were private businesses (15.4%), non-profit and international organizations (14.5%), and other non-identified organizations (18.2%). Willingness to pay for training would be a strong indicator on demand for training, but the relevant data are not available from the survey.

The analysis of the results in terms of current labour force status shows that more than half of the persons who participated in training programmes last year were current employed (58%), some were currently unemployed (3.3%), and the remainder were currently outside the labour force (36%).

It is also instructive to note that the current labour force participation rate of participants in training programmes was considerably higher than those who did not

participate in training programmes. Figure 27 compares the labour force participation rate of the training participants and the national labour force participation rate. As it can be observed the rate of the training participants is uniformly higher than the national rate for both men and women as well as in urban and in rural areas.

Fig. 27 Current labour force participation rate of persons with training last year compared with national LFPR

The next figure (Fig. 28) the current unemployment rate of participants in training programmes last year with the national unemployment rate. The results show that the training participants have lower current unemployment rate (8.7%) than the national rate (13.5%). Similar results are obtained for men and rural areas, separately. For women and urban areas, however, the unemployment rates among the training participants are higher than the corresponding national rates, 28.6% versus 26.1% for women, and 16.6% versus 12.4% in urban areas.

Fig. 28 Current unemployment rate of persons with training last year compared with national UR

The result suggests that women and persons in urban areas who participate in training programmes are eager to get into the labour market, and many of them do but the barriers to get employment are stronger than for men and persons in rural areas.

11. Migrants working abroad

The special module on labour migration attached to the labour force survey collected data on former household members currently living abroad. In each sample household, an inquiry was made to identify if a former household is currently living abroad. In the case of a positive reply, further information were obtained on the demographic and employment characteristics of the persons living abroad such as sex, age, education attainment and the current and past labour force status, occupation and branch of economic activity. The results have been processed and presented in the last set of statistical tables of Annex A of the present report. It should be borne in mind that the scope of the data is limited to those Yemenis of working age living abroad who have maintained a family relationship with the resident households. As such the data don't cover all Yemenis living abroad.

According to the results shown in Figure 25, there were 103,000 Yemeni migrants of working age living abroad in 2013-14, 102'000 men (99%) and 1'000 women (1%). This means that overall, roughly for of every 200 residents there was one migrant of working age living abroad. The educational attainment of the great majority was primary education (70%). In terms of age structure, most were in the age category, 25 to 34 years old (37%) or 35 to 54 years old (31%).

The largest numbers of migrants living abroad were from Ibb and Taiz. In relation to their population, Hadramout and Shabwah are the governorates with the highest percentage of migrants living abroad. An estimated 23,000 migrants living abroad are coming from urban households and 83,300 from rural households, almost in proportion to the respective resident populations living in urban and rural areas.

Fig. 29 Migrants of working age living abroad
by sex, age group and educational attainment, LFS 2013-14

Almost half of the migrants working abroad were unemployed prior to leaving Yemen. Almost one-third were employed and the remaining one-sixth going outside the labour force, mostly in school or at home with family responsibilities. Virtually all have obtained employment abroad (93%), but some have remained or become unemployed (5%). Those outside the labour force were generally women accompanying their spouses working abroad.

Table 9 compares the main labour force indicators of the migrants living abroad prior and after leaving Yemen. The results show that prior to leaving the country, most migrants were unemployed (50,600) as reported by the members

Table 9. Prior and current labour force status of migrants of working age living abroad, LFS 2013-14

	Prior status before leaving Yemen	Current status abroad
Employed	34,400	96,500
Unemployed	50,600	4,800
Outside the labour force	18,400	2,100
Labour force participation rate	82%	98%
Employment-to-population ratio	33%	94%
Unemployment rate	60%	5%

of their former households. An estimated 34,400 were employed prior to leaving the country and about 18,400 were outside the labour force, neither employed or unemployed. As the data suggest, the labour force status of the migrants considerably changed after leaving the country: virtually all were employed in the country they currently live; the current status of only 4,800 persons was unemployed.

Accordingly, the employment-population ratio of migrants living abroad indicates a larger increase from 33% prior to migration to 94% after migration. Correspondingly, the unemployment rate of migrants living abroad shows a very large decrease from 60% prior to migration to 5% after migration. The change in the labour force participation rate has been milder due to the shift from unemployment to employment within the labour force.

The results although significant should be interpreted cautiously as the underlying data are likely to be subject to considerable errors. They are based on proxy-response and recall of persons who may have limited information on the past and current activity of the migrant workers who are no longer members of the responding household. The great majority of the migrants have been away for more than 1 year. More than 40% have been living abroad more than 5 years. Also, there may be considerable exaggeration in the responses as former household members may think or may want to show the success of their migrant former household members.

Despite these difficulties, the results of the survey have been further processed to compare the current employment characteristics of the migrants working abroad with the corresponding characteristics prior to migration as reported by their former household members. Table 10 provides data by current and prior branch of economic activity.

Table 10. Migrants working abroad by current and former branch of economic activity, LFS 2013-14

		Former branch of economic activity				
		AGR	IND	SER	Total	%
Current branch of economic activity	AGR	800	0	300	1,100	3%
	IND	4,300	7,400	3,100	14,800	37%
	SERV	6,300	4,300	13,300	23,900	60%
	Total	11,400	11,700	16,700	39,800	100%
	%	29%	29%	42%	100%	

Note: AGR = Agriculture, hunting, forestry and fishing; IND = Industries covering Mining and quarrying, manufacturing, Electricity, gas and water supply, and construction; SER = Services including Wholesale, retail trade; repair of motor vehicles, Hotels and restaurants, Transport, storage and communications, as well as Education, Health and social work, and Other community, social and personal service activities.

The results show that the main movement was from agriculture to services. Among the migrants working abroad who were also employed prior to migration, 29% were engaged in agricultural activities. In their current activity after migration, only 3% are in agriculture. The percentage of migrants who were working in services prior to migration was 42%. The corresponding percentage after migration is 60%. The shift from agriculture to services shows the highest movement, involving some 6,300 migrants workers. Migrants currently engaged in industry or services were in the most part also engaged in the same branch of economic activity prior to migration.

Further analysis on more detail branches of economic activity and by occupation may be carried based on the statistical tables provided in Annex A of the present report.

Annex A. Statistical tables

NOTES:

1. *For convenience the data in some tables, especially where small cases observed, are presented in exact numbers, although due.*

to sampling variations the last two or three digits are not always statistically significant.

2. *Due to the missing values on the cross classification variables details written a table,*

a. Totals in a table may not equal to the totals given in the table, and

Annex B. Survey methodology and data quality

1. Survey design

The survey was designed to meet five main measurement objectives as follows:

- To provide current data on the number of employed, unemployed, and underemployed, and their demographic and social characteristics, including the size of women's participation in economic activity with a view to future policies in expanding their participation in the labour market;
- To collect data on qualifications of the labour force and participation in training programmes of the youth population and other data requirements for improving the performance of employers through knowledge on the levels of skill available to them;
- To measure the volume and characteristics of labour migration of Yemenis outside the country;
- To provide information on the amount of wages and employment-related income in different occupations, branches of economic activity and sectors of employment;
- To collect appropriate data for evaluating the microfinance projects funded through the Social Fund for Development.

Given the extent and diversity of data requirements, the survey was designed to spread over a one-year period, built around the five objectives of the survey. The core labour force survey was conducted throughout the four quarters of the survey period and incorporated the measurement of income from employment along the conventional items of data collection. Data on qualifications and participation in training was collected on the third quarter and on labour migration on the second quarter of the survey programme. Data collection on microfinance was undertaken as a separate survey over the four quarters.

Like in previous household surveys, the labour force survey covered the civilian non-institutional settled population excluding certain areas with difficult access or low population densities, in particular, the nomad population, displaced populations who are homeless, population living in public housing (boarding, hotels, prisons, hospitals, etc.), individuals enlisted in the Armed Forces, who are residing permanently within camps and do not spend most days of the year with their families. Similarly, for marine crews and expatriates outside the country and other categories of persons in remote islands.

Survey operations were carried out in all governorates except parts where recent events have disturbed the normal course of economic activity. In these circumstances, special procedures were used for compensation, either through the replacement of those areas with other areas having otherwise similar characteristics in the respective strata or through the adjustment of the sampling weights for missing values. There were 14 such cases, 5 each in quarters 1 and 4, and 2 each in quarters 2 and 3.

2. Sample design

The sample design of the labour force survey of Yemen 2013-2014 is a two-stage stratified sample of enumeration areas in the first stage of sampling and a fixed number of

sample households at the second stage of sampling. The resulting sample is spread evenly over the four quarters of the survey period.²¹

Accordingly, the Central Statistics Organization (CSO) has drawn a stratified sample of census enumeration areas recomposed as primary sampling units (PSUs). Sample selection has been made with probability proportional to the number of households as determined in the 2004 population census. In the second stage of sampling, after relisting of the sample enumeration areas, a fixed number of households (16 sample households) are drawn as clusters with equal probability from each sample enumeration area. The strata consist of the urban and rural areas of the 21 governorates in Yemen. The distribution of the enumeration areas and sample households by governorate and by urban and rural location for all four quarters is given in Table B1 below.

Table B1. Sample enumeration areas and sample households: All quarters

Governorate	Total		Urban		Rural	
	EAs	Hslds	EAs	Hslds	EAs	Hslds
Yemen	836	13376	416	6656	420	6720
11 Ibb	64	1024	28	448	36	576
12 Abyan	32	512	16	256	16	256

14 Al Bayda	32	512	16	256	16	256
15 Tai'izz	76	1216	36	576	40	640
16 Al Jawf	28	448	12	192	16	256
17 Hajjah	48	768	16	256	32	512
18 Al Hudaydeh	76	1216	40	640	36	576
19 Hadramaut	52	832	32	512	20	320
20 Dhamar	48	768	20	320	28	448
21 Shabwah	28	448	12	192	16	256
22 Sa'dah	36	576	16	256	20	320
23 Sana'a	32	512	8	128	24	384
24 Aden	36	576	36	576	0	0
25 Lahij	36	576	12	192	24	384
26 Ma'rib	20	320	8	128	12	192
27 Al Mahwit	28	448	8	128	20	320
28 Al Mahrah	16	256	8	128	8	128
29 Amran	36	576	16	256	20	320
30 Ad Dali	28	448	12	192	16	256
31 Raymah	20	320	4	64	16	256

According to the sample design, urban areas are oversampled and rural areas under-sampled. This is because a relatively larger sample size is required in urban areas where heterogeneity is greater in comparison with rural areas. Also, because the cost of transportation and field operations is relatively greater in rural areas, it is more cost effective to under sample the rural areas relative to the less costly operations in urban areas. The differential sampling rates are then corrected through the sample weights so that the final results accurately reflect to the overall employment pattern.

The sample selection of the cluster of 16 households in each sample enumeration area was drawn after fresh listing of the totality of the households living in the sample enumeration area at the time of listing. This procedure updates the census information that dates back to 2004. The listing operations are carried out in each quarter before survey

²¹ *Yemen Labour Force Survey 2013: Proposed Survey Programme*, Farhad Mehran, ILO Consultant, Unpublished report, 7 July 2012.

interviewing. The updated lists are sent to CSO in Sana'a for data entry and sample selection of households for transmission to the survey team in each area. Instructions were given so that sample households that could not be found in the field or were absent or refused to be interviewed should not be substituted with other households as this procedure may introduce bias in the results. Instructions were also given that in cases where the minimum number of households in the sample enumeration areas was to be found to be less than the required 16 in each quarter, all households in the enumeration area should be taken in the sample.

The sample size in terms of number of sample households is given in Table B2 below for each quarter and for urban and rural areas separately. The effective sample size was lower due to non-response and other problems of coverage.

Table B2. Number of sample households by urban-rural location for each quarter

	Total	Urban	Rural
Q1	3344	1664	1680
Q2	3344	1664	1680
Q3	3344	1664	1680
Q4	3344	1664	1680
Total	13376	6656	6720

The total sample size was determined on the basis of the requirement of producing national estimates of the unemployment rate with 1.5% margin of errors at the national level, assuming an overall non-response rate of 15%, and a design effect of 3. For the determination of the national sample size, the expected unemployment rate was set at 15% and the expected number of sample households to reach one person of working age, 15 years old and over, in the labour force was set at 0.6.

3. Sampling weights

In order to obtain estimates of population aggregates, the sample results were extrapolated using sampling weights.²² The sampling weights were calculated on the basis of the sample design and response rates. The sample design determines the probability of selection of each unit that in principle is a known non-zero value between 0 and 1. The response rates were obtained from information on the cover page of the LFS questionnaire after visiting the sample household: completed interview, partially completed interview, absent, refusal, vacant/demolished, out-of-scope (shop, workshop, office, ...) and other.

In mathematical terms, the extrapolation weights are given by

$$w_k = \frac{BasicWeight}{ResponseRate}$$

where the basic weight is the inverse of the probability of selection and the response rate in the proportion of completed and partially completed households interviewed in the total number of sample households selected.

For the calculation of the probability of selection, the number of households listed is obtained from the listing form and the number of sample households selected is the

²² *Yemen Labour Force Survey 2013-2014: Sampling weights*, Farhad Mehran, ILO Consultant, Unpublished report, April 2014.

sample-take, the fixed number of sample households selected in each sample enumeration area, $b=16$. The number of sample households with completed and partially completed interviews is obtained from the cover page of the filled-in household questionnaire. The probability of selection of the sample enumeration area is proportional to size to the number of households in the sample enumeration area according to the sampling frame.

Finally, the extrapolation weights were adjusted to conform to known population projections. This process of adjustment is called calibration. Calibration means using calibrated weights such that the application of these weights to the auxiliary variables will give estimates exactly equal to the known population totals on those auxiliary variables. Here calibration was made on the sampling weights of all quarters except the first to conform to the projected population of the quarters based on the population estimate of the first quarter. This procedure was adopted because independent and reliable projection projections were not available.

For the calculation of annual estimates, the quarterly sampling weights were simply divided by four. This procedure is equivalent to calculating annual estimates by the simple arithmetic average of the quarterly estimates. Table 3B below provides summary statistics on the size distribution of the final calibrated sampling weights for the survey year as a whole and each quarter separately. by quarter in rounded figures.

Table B3. Summary statistics on the size distribution of the final calibrated sampling weights

	Average sampling weights	Standard deviation
Q1	1038	734
Q2	1073	838
Q3	1123	1167
Q4	1219	1665
Annual	277	284

The results indicate that on average on each sample person represents about 1100 persons for quarterly estimates and about 277 persons for annual estimates. The standard deviations of the quarterly or annual weights are about equal the average weights, indicating significant variability among the sampling weights, whether quarterly or annual.

4. Main concepts and definitions

The main concepts and definitions used in the survey are in with the international standards on statistics of work, employment, and labour underutilization adopted by the Nineteenth International Conference of Labour Statisticians (Geneva, 2013).²³ They are briefly described below.

- Work

The starting point of the international standards on statistics of work, employment and labour underutilization is the concept of work defined as:

²³ ILO, *Resolution concerning statistics of work, employment and labour underutilization*, Nineteenth International Conference of Labour Statisticians, Geneva, October 2013.

- “Any activity performed by persons of any sex and age to produce goods or to provide services for use by others or for own use” in line with the General production boundary defined in the System of National Accounts 2008.
 - Work is defined “irrespective of its formal or informal character or the legality of the activity.”
 - It excludes “activities not involving production of goods or services (begging, stealing), self-care (personal grooming, hygiene) and activities that cannot be performed by another person on one’s own behalf (sleeping, learning, own recreation).”
- Employment

Employment is a particular form of work.²⁴ Persons in employment are defined as all those above a specified age who, during a short reference period, were engaged in any activity to produce goods or provide services for pay or profit. It excludes persons engaged wholly in activities to produce goods or services for own final use such as producing agricultural, fishing and gathering products for own-consumption or cleaning, decorating, gardening and maintaining one’s own dwelling or premises, durables and other goods. Persons in employment comprise: (a) employed persons “at work,” i.e., who worked in a job for at least one hour; and (b) employed persons “not at work” due to temporary absence from a job, or to working-time arrangements (such as shift work, flexi-time and compensatory leave for overtime).

- Unemployment

Persons in unemployment are defined as all those above a specified age who (a) were not in employment; (b) carried out activities to seek employment during a specified recent period; and (c) were currently available to take up employment given a job opportunity. The definition of unemployment provides an exception in the case of *future starters*. They are considered as unemployed even if they did not carry out activities to seek employment during the specified recent period, criterion (b) as long as they satisfy the availability condition.

- Time-related underemployment

Persons in time-related underemployment are defined as all persons in employment who, during a specified reference period, (a) wanted to work additional hours, (b) whose working time in all jobs was less than a specified hours threshold, and (c) who were available to work additional hours given an opportunity for more work. In the Yemen LFS, the hour-threshold was set at 35 hours usually worked per week, on the basis of the weighted median of the distribution of hours usually worked of reporting survey units.

- Potential labour force

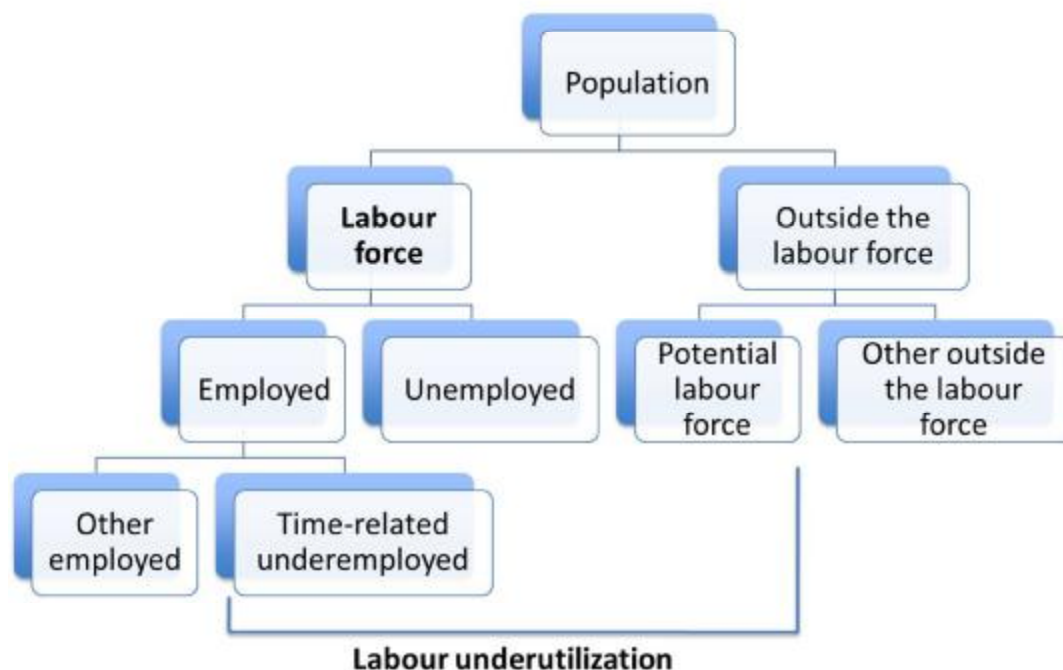

Potential labour force is defined as all persons above a specified age who, during the short reference period, were neither in employment nor in unemployment but who were considered as either (a) unavailable jobseekers (seeking employment but not currently

²⁴ Other forms of work recognized by the international standards are own-use production work, unpaid trainee work, and volunteer work.

available) or (b) available potential jobseekers (currently available for employment but did not carry out activities to seek employment).

The relationship among the various concepts is show in Figure B1 below.

Fig. B1 Labour force and labour underutilization framework

- Own-use producers

Persons in own-use production work are defined as all those of working age who, during a short reference period, performed any activity to produce goods or provide services for own final use for a cumulative total of at least one hour. “For own final use” is interpreted as production where the intended destination of the output is mainly for final use (in the form of capital formation, or final consumption by household members, or by family members living in other households). In the case of agricultural, fishing, hunting or gathering goods intended mainly for own consumption, a part or surplus may nevertheless be sold or bartered.

Subsistence foodstuff producers constitute an important subgroup of persons in own-use production work. They are defined as all those who performed any of the specified activities to produce foodstuff from agriculture, fishing, hunting or gathering that contribute to the livelihood of the household or family. Excluded are persons who engaged in such production as recreational or leisure activities.

Own-use producers and in particular subsistence foodstuff producers (and for that also matter unpaid trainee workers or volunteer workers) may be engaged, in the same reference period, in other activities, including employment or search for employment. On the basis of their other activity, therefore, certain own-use producers may also be in the

labour force and classified as employed, unemployed or other labour underutilization category.

Table B4 lists the terminology and definitions of the main labour force and labour underutilization indicators used in the survey. The definitions of other concepts used in the survey such as vulnerable employment, informal employment, skill-related and income-related inadequate employment situations are given directly with the descriptive analysis of the subject.

Table B4. Main labour force and labour underutilization indicators

Concept	Definition
Working age population (Pop15+)	$E+U+N$
Labour force (LF)	$LF=E+U$
Potential labour force	P
Extended labour force (XLF)	$XLF=E+U+P$
Employment	E
Unemployment	U
Time-related underemployment	T
Labour force participation rate	$LF/Pop15+$
Employment-population ratio	$E/Pop15+$
Unemployment rate (LU1)	U/LF
Combined rate of unemployment and time-related underemployment (LU2)	$(U+T)/LF$
Combined rate of unemployment and potential labour force (LU3)	$(U+P)/XLF$
Composite measure of labour underutilization (LU4)	$(U+T+P)/XLF$

The definitions of other concepts used in the survey such as status in employment, informal sector and informal employment are described as part of the analysis of the data in the body of the report.

5. Questionnaire design

The questionnaire of the Yemen LFS 2013-14 was designed on the basis of the ILO model LFS questionnaire (version A) and other national LFS questionnaires used in the region. The draft questionnaire was field tested with six households in Sana'a, each member of the field staff interviewing one sample household in his or her area. The experience gained in the field test was reviewed and led to some modifications of the draft questionnaire. The English version of the final questionnaire is reproduced in Annex C of the revised report.

Apart from the cover page and the back page, the core LFS questionnaire contains 52 questions. There are 11 questions on the social and demographic characteristics of the household members in the household roster. In the individual questionnaire addressed to the working age population 15 years of age or older, there are 3 questions to identify the employed persons and 19 questions on their employment characteristics including time-related underemployment followed by 8 additional questions on income from employment. The individual questionnaire also includes 5 questions to identify the unemployment and the potential labour force and 5 follow-up questions on unemployment characteristics.

The flow charts specifying the combinations of questions and answer categories used for measuring the main indicators of the survey, namely, employment, unemployment, time-related underemployment, and potential labour force are presented in Figures B2 to B5.

Fig. B2 Derived variable: Employment (E)

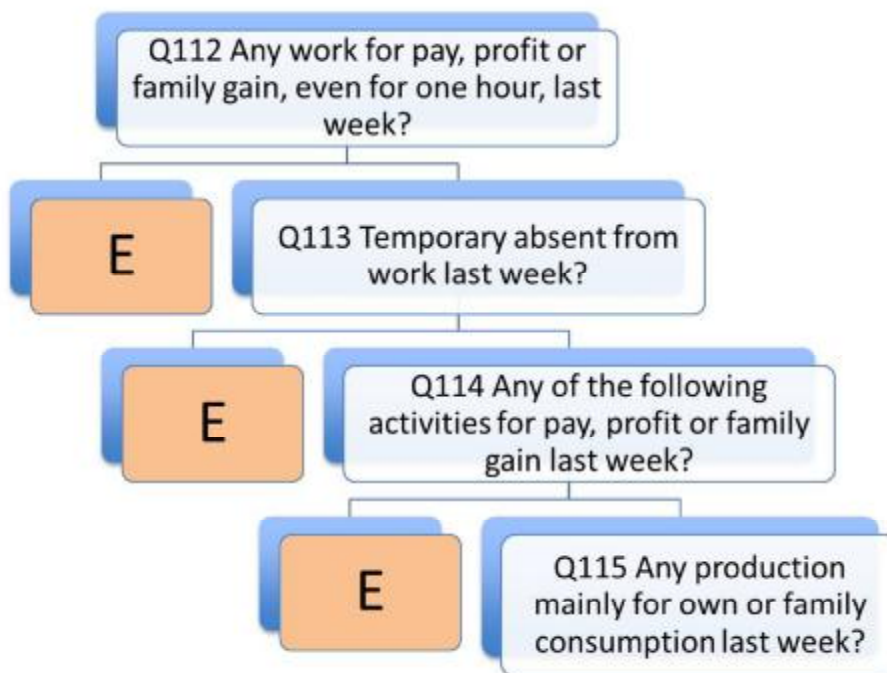

Fig. B3 Derived variable: Unemployment (U)

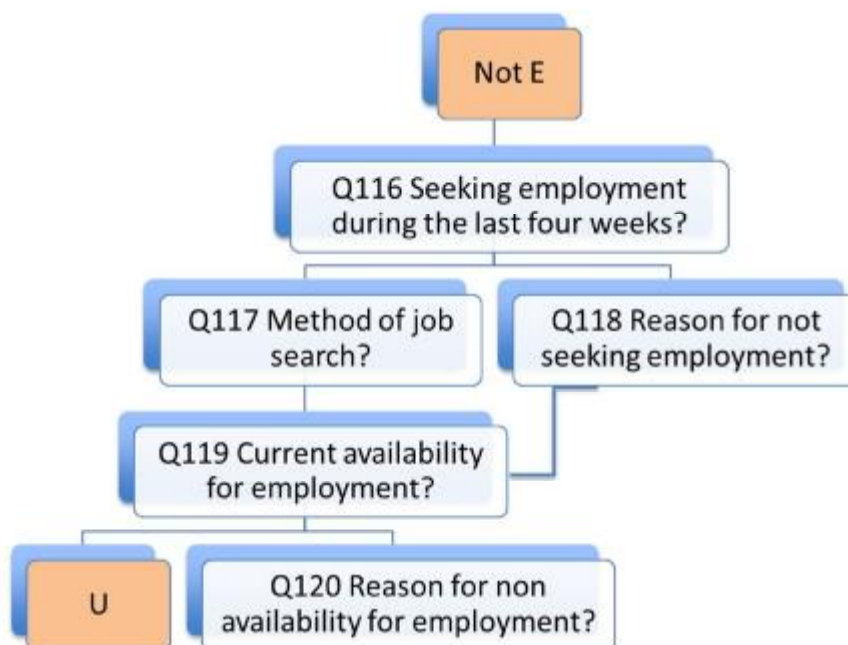

Fig. B4 Derived variable: Time-related underemployment (TRU)

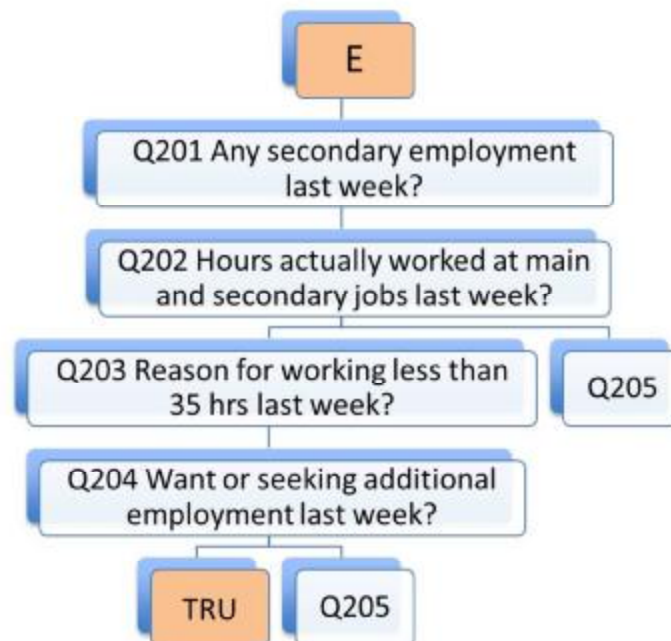

Fig. B5 Derived variable: Potential labour force (PLF)

U = Unemployed including future starters (Q116=1 and Q119=1)

PLF = Potential labour force excluding future starters

N = Other persons not in labour force

6. Field operations and data processing

- Field operations

The field operations of the labour force survey were launched in September 2013. The field staff was composed of 60 interviewers, 21 team leaders and 22 supervisors. The same team with one car covered both the urban and rural areas within each governorate. The operations may be grouped into two major steps: (a) complete listing of households in 209 sample enumeration areas (Primary sampling units) in each quarter; and (b) interviewing of 16 selected sample households in each of the sample enumeration areas..

The listing operations were meant are to update the sampling frame based on the population and housing census 2004, and to account for new household formations and population movements that has occurred since 2004. Table B5 compares the number of households obtained during the listing operations for the LFS 2013-14 with the corresponding number for the sample enumeration areas according to the population census 2004.

Table B5. Listing in LFS 2013- versus Population Census 2004
(472 sample enumeration areas)

	Number of households		Difference	
	Pop 2004	LFS 2013-14	number	%
Q1	27'736	30'206	2'470	8.9%
Q2	28'765	29'972	1'207	4.2%
Q3	28'703	27'926	-777	-2.7%
Q4	28'362	28'1756	-187	-0.7%
Total	113'566	116'279	2'713	2.4%

The large over all difference between the numbers of households according to the population census 2004 and those obtained from the listing operations of LFS 2013-4 reflect population growth between the two periods. The difference is particularly noticeable in Q1. In Q2 the difference gets smaller and even negative in Q3 and Q4, possibly indicating a certain lassitude in the listing operations.

Survey interviewing was carried from 17 August 2013 to 1 September 2014 for quarter 1; 2 to 17 November 2014 for quarter 2; 1 to 16 February 2014 for quarter 3; and 1 to 16 May 2014 for quarter 4. The interviewers were recruited from outside Central Statistical Organization through newspaper advertisements. They received training during a five-day period: three days for classroom training, 1 day for pilot interviewing and 1 day for evaluation.

- Data processing

Data processing involved data entry, coding, editing and tabulation of the survey results. Data entry was carried out in parallel with the interviewing of sample households. It was conducted at the Central statistical Organization headquarter in Sana'a where all data processing operations except tabulation were centralized.

The supervisory staff of the data entry operations was responsible for editing the questionnaires before actual data entry. Editing at this stage involved review of the

questionnaire regarding its filled-in contents including ensuring that there are no missing block of information for household members aged 15 years old and over and correct coding of occupation, branch of economic activity and other variables.

Occupation was coded at the 6-digit level using the International Standard Classification of Occupations (ISCO-88). Branch of economic activity was coded at the 5-digit level, based on the International Industrial Classification of All Economic Activities (ISIC Rev3.1).

The data files were further processed at ILO headquarters in Geneva. They were first converted into a single file with 86,778 records and augmented with several fields, in particular, the sampling weights ("weight") and the key derived variables: employed (E), unemployed (U), time-related underemployment (TRU), potential labour force (PLF) as well as other derived variables such as informal sector employment (IS) and informal employment (IE).

The augmented file was then used to tabulate the results using STATA as presented in Annex A of the present report. The following rounding rule was adopted for the presentation of the results. Estimates of levels are rounded to three zeros ('000) for values equal or above 1000. Estimates of percentage rates are rounded to the first decimal point. In interpreting the published results, attention should be made to the sampling variation of the estimates as described in the next section.

7. Data quality and evaluation of the results

Like in all sample surveys, the results of the Yemen Labour Force Survey 2013-14 are subject to sampling and non-sampling errors.

- Sampling errors

Sampling errors arise due to the fact that the survey does not cover all elements of the population, but only a selected portion. The sampling error of an estimate is based on the difference between the estimate and the value that would have been obtained on the basis of a complete count of the population under otherwise identical conditions.

Knowing about the magnitude of sampling errors is crucial for interpreting the survey results. It allows decision on the precision of the estimates and on the degree of confidence that may be attached to them, especially relevant in the case of small population subgroups for which the survey results may not be statistically significant due to the small number of observations on which the estimates may be based. Information on sampling errors is also crucial for sample design for future surveys.

In principle, sampling errors may be decomposed into two components: (i) sampling bias; and (ii) sampling variance. Sampling bias reflects the systematic error that may occur due to the failures of the sample design, for example, certain elements of the population receiving zero probability of selection. The sampling variance, on the other hand, reflects the uncertainty associated to a sample estimate due to the particular sample used for its calculation, among all possible other samples that could have been selected from the frame with the same sampling design.

The calculation of the sampling variance of survey estimates for complex multi-stage designs is generally based on the following principle: the variance contributed by the later stages of sampling is, under broad conditions, reflected in the observed variation among the sample results for first-stage units. Thus, the sampling variance of a variety of statistics, such as totals, means, ratios, proportions, and their differences can be obtained on the basis of totals calculated for primary sampling units (PSUs).²⁵

Table B6 below gives the estimates of the main labour force indicators and their standard errors for the LFS 2013-14 calculated on the basis of the results of Q1 and annualized over the four quarters.

Table B6. Standard errors of main labour force indicators
LFS 2013-14

	Estimate	Standard error		Confidence interval	
	'000	'000	%	- '000	+ '000
Working age population	13,378	181	1.4%	-354	354
• Labour force	4,850	65	1.4%	-128	128
- Employed	4,197	61	1.5%	-119	119
(of which time-related underemployed)	9	1	11.4%	-2	2
- Unemployed	653	24	3.8%	-48	48
• Outside the labour force	8,528	136	1.6%	-267	267
(of which potential labour force)	894	31	3.5%	-61	61
Own-use producers	3,270	110	3.4%	-215	215
Labour force participation rate	36.3%	-	0.3	-0.6	0.6
Employment-population ratio	31.4%	-	0.3	-0.6	0.6
LU1. Unemployment rate	13.5%	-	0.5	-1.0	1.0
LU2. Unemployment & time-related underemployment	13.6%	-	0.5	-1.0	1.0
LU3. Unemployment & potential labour force	26.9%	-	0.6	-1.2	1.2
LU4. Composite measure of labour underutilization	27.1%	-	0.6	-1.2	1.2

One use of the standard deviation is to assess the level of precision of survey estimates. A low relative standard deviation indicates a high precision of the estimate. In general, the lower the relative standard deviation of an estimate, the higher is the precision of the estimate. The relative standard deviation of an estimate is the ratio of the standard deviation to the size of the estimate. Thus, the working age population and the labour force, with relative standard deviations of 1.4%, are estimated with slight more precision than employment, relative standard deviation of 1.5%. The results also show that unemployment and time-related underemployment are the estimates with the least precision respectively, 3.8% and 11.4%.

The bottom rows left of the table give the standard deviations of estimates of ratios. It shows that the labour force participation rate and the employment-population ratio are estimated with standard deviations at 0.3 percentage points, while the unemployment rate and the other indicators of labour underutilization are estimated with standard deviations of around 0.5 percentage points.

Another use of the standard error is for the calculation of confidence intervals. Under certain broad assumptions, it can be stated that the true value of the variable of

²⁵ *Yemen Labour Force Survey 2013-2014: Sampling errors*, Farhad Mehran, ILO Consultant, Unpublished report, April 2014.

interest lies in between the survey estimate and a multiple of the standard error, with certain degree of probability. Thus, referring to the results shown in Table B6, it can be stated, for example, that the 'true' value of the total number of unemployed is within the interval,

$$653,000 - 1.96 \times 24,000 \leq \theta \leq 653,000 + 1.96 \times 24,000$$

$$653'000 - 48,000 \leq \theta \leq 653'000 + 48,000$$

where 1.96 is the value of the standard normal distribution corresponding to 95% confidence probability and 24'000 is the standard deviation of the estimate of unemployment.

As it is not practical to compute and report sampling variances and standard deviations for every published statistics of the labour force survey, it is customary to calculate general standard errors using an approximate relationship between the variance of an estimate and its size. The results are shown in Table B7.

Table B7. Generalized standard errors
LFS 2013-14

Estimate	Standard error		Confidence interval	
'000	'000	%	- '000	+ '000
10,000	115	1.2%	-225	225
5,000	78	1.6%	-152	152
2,000	47	2.4%	-92	92
1,000	33	3.3%	-64	64
500	23	4.6%	-45	45
200	14	7.2%	-28	28
100	10	10.2%	-20	20
50	7	14.3%	-14	14

It can be observed that estimates with high values, more than 10 million, have relative standard deviation less than 1.7% and the confidence intervals (margins of errors) around +/- 225,000. At the other extreme, estimates below 50'000 have high relative standard deviations more than 14.3%, and margin of errors around 14,000.

As an example of the use of Table B7, consider the calculation of the standard error of the survey estimate of total informal employment, 3,416,600 as reported in Section 6 of the report. With reference to the values of Table B7, the level of the estimate is between 2,000,000 and 5,000,000. Therefore, the approximate standard error of the estimate is between 47,000 and 78,000, or more precisely by interpolation, 62,000. (The actual estimate of the standard error of the informal employment calculated directly is 61,500.)

Corresponding generalized standard errors for estimates of ratios have been calculated and may be found in *Yemen Labour Force Survey 2013-2014: Sampling errors*, Unpublished report, April 2014.

In addition to sampling errors, survey data are subject to different types of non-sampling errors (coverage errors, non-response errors, response errors, and other errors such as editing, coding and processing errors).

- Coverage errors

Probability sampling requires each element in the target population to have a known non-zero probability of being selected in the sample. This condition is violated if the target population is not fully represented in the sample frame or if the sample selection of units from the frame is not according to the procedures specified in the sample design. The violation of these conditions generates coverage errors.

Coverage errors may occur due to imperfect frame (under-coverage, over-coverage, or duplication of units) or to practical problems such as confusion in boundary of units or in rules of association between units of different types. Coverage errors may also occur at the stage of selection of individual persons in the sample household because of failure to identify some eligible persons, for example, lodgers, domestic workers or other non-family members of the household. It can even happen due to incorrect data on personal characteristics, for example, if the age of the person is incorrectly recorded as below the age set for measuring labour force characteristics (under-coverage error), or vice versa the age is incorrectly recorded as above the threshold age (over-coverage error).

A measure of coverage errors in the LFS 2013-14 is obtained by comparing the number of households in the sampling enumeration area obtained during the listing operations with the corresponding number according to the population census 2004, discussed earlier in connection with Table B5.

- Non-response errors

Non-response occurs due to failure to obtain the required information from the units selected in the sample (unit non-response) or to failure to obtain some items of information for the selected unit (item non-response). Unit non-response may occur due to incorrect address of the sample household, or inaccessibility of certain dwellings or refusal of the sample household to be interviewed, or because no one was at home when the interviewer contacted the household, or for other reasons. Vacant or demolished dwellings, non-existent or out-of-scope addresses, such as finding an enterprise or workshop instead of a household dwelling, are not generally considered as unit non-response.

Table B8 shows the interview results in terms of response and non-response. Among the 13,167 target sample households, some of 12,646 provided data for all members of the households and 16 for some but not all members. In addition, 323 eligible sample households could not be contacted due to temporary absence and 155 refused to participate in the survey. There were also 11 sample households who could not be contacted because the dwelling was found vacant or the address could not be found. Finally, there were 2 sample dwellings found destroyed and an additional 14 that could be interviewed for other reasons.

Table B8. Response and non-response of sample households
LFS 2013-14

	Total	Response	Non-response	Non-eligible
Total	13,167	12,662	478	27
Completed (Fully responding households)	12,646	12,646	-	-
Partial (Missing individual questionnaires)	16	16	-	-
Not in house (Temporary absent)	323	-	323	-
Refusal	155	-	155	-
No contact (Vacant, address not found)	11	-	-	11
Destroyed	2	-	-	2
Out of scope	0	-	-	0
Other reasons	14	-	-	14

In total, there were 13,140 eligible households, among which 13,140 responded and 478 not responded, giving a non-response rate of 3.6%. The non-response rate was about the same in all quarters (4.4% in Q1, 3.3% in Q2, 2.8% in Q3 and 4.0% in Q4). Corrections for non-response errors were made by inflating the design weights for each quarter by the inverse of the response rate (one minus the non-response rate defined above) for each sample enumeration area as described earlier. This procedure assumes that non-respondent households within an enumeration area have similar characteristics as the responding households in those areas.

- Response errors

Response errors refer to errors originating at the data collection stage. In relation to an individual respondent, response errors may occur because the respondent was unwilling to divulge certain information or because the respondent did not know the answer to the question asked or did not fully understand the meaning of the question. Response errors can also occur due to memory lapses, for example by forgetting to report an event, or incorrectly reporting its timing. Response errors may also occur because of errors made by the interviewer or by the instrument used for measurement. Interviewers may introduce errors because of haste and misreporting the responses, or because of misunderstanding of the survey concepts and procedures, or preconceptions and subjective biases. The questionnaire itself may be faulty, with wrong question wordings and incorrect skipping patterns.

The measurement of response errors is one of the most difficult parts of quality assessment of survey data. It generally requires carefully designed re-interview programmes. In the absence of such data, the quality of survey responses may be assessed by measuring the degree of self-response against proxy-response, or by testing the internal consistency of certain sets of inter-related responses, or by comparison of the survey results with corresponding information from more reliable external sources such as administrative sources. The results for on primary and secondary school teachers are shown in Table B9 and for employees in public administration in Table B10.

Table B9. Comparison of LFS and Administrative data on primary and secondary education teachers

	Yemen LFS 2013-14 ¹	Administrative source ² 2012-13	Difference
Total teachers in primary and secondary education	171,722	229,405	-57,683
- Primary education teaching professionals	106,675	125,222	-18,547
- Secondary education teaching professionals	65,047	104,183 ³	-39,136

Notes: ¹Yemen Labour Force Survey 2013-14, Central Statistical Organization, Yemen, Table 16. Data on LFS 2013-14 concern main jobs. The difference with the administrative source may partly due to this reason.

²Statistical Yearbook 2013, Central Statistical Organization, Yemen (Education, Table 7).

<http://www.cso-yemen.org/content.php?lng=english&id=661>

³Includes teachers in both basic and secondary education.

The total number of teachers in primary and secondary education from the administrative source (229,405) is substantially higher than the corresponding estimate from the labour force survey (171,722). In relative terms, the difference is more significant for secondary education than for primary education. The difference between the two sources may be due to differences in definitions and classifications. The survey estimates refer to teachers in their main jobs, while the administrative source cover all teachers, whether those on their main or secondary activity.

Table B10. Comparison of LFS and Administrative data on public administration employees

	Yemen LFS 2013-14 ¹	Administrative source ² 2013	Difference
Employment in public administration and defense; compulsory social security	533,444	589,806	-56,162
- Male	518,493	484,649	+33,844
- Female	14,952	105,157	-90,205

Notes: ¹Yemen Labour Force Survey 2013-14, Central Statistical Organization, Yemen, Table 13. Data on LFS 2013-14 concern main jobs. The difference with the administrative source may partly due to this reason.

²Statistical Yearbook 2013, Central Statistical Organization, Yemen (Labour force, Table 7, Number and Percent Distribution of Civil Servants (Permanent Staff) in the Judicial and administrative Organization of the Country and in the Public and Mixed Sectors by Governorate and Sex for :2011-2013).

<http://www.cso-yemen.org/content.php?lng=english&id=661>

The number of civil service employees from the administrative source (589,806) is about ten percent higher than the corresponding estimate from the labour force survey (533,444). The unaccounted difference (-56'162) may be partly due to civil service employees classified in other branches of economic activity in the labour force, for example, civil service employees employed in public radio and television institutions, or national

museums or embassies abroad. The differences between the survey estimates and the administrative source are larger than the sampling errors, especially, for women employees.

Other comparisons with administrative sources may be performed, for example, comparing the survey estimate of the number of unemployed jobseekers reporting to be registered at the labour office or at civil service bureau with the corresponding data from the administrative source.
